The Davis Regulator —a safe investment

A SURE way to increase dividends is by installing dividend paying equipment—Davis Regulators, for instance. The cost of these dependable regulators is small and their saving is as certain as their operation.

Cut down the high boiler pressure to just the pressure you need for each service requiring steam. Unless you have already given attention to pressure regulation you can expect 100 per cent annual dividends on all the Davis Regulators for which you have applications.

Davis Regulators are nationally

priced and their ability to save steam, coal and dollars is nationally known. It requires less attention, lasts longer, and gives steadier, more accurate pressure reduction. No springs; no toggles; no diaphragms; no packing—just a finely balanced inner valve. When you buy one of these old reliable regulators you agree to demand your money back if it fails to give perfect satisfaction.

Write the G. M. Davis Regulator Co., 409 Milwaukee Ave., Chicago, for descriptions of this and the many other Davis Valve Specialties.

THE Davis Regulator will reduce any initial pressure to any desired delivery pressure and maintain the lower pressure constant. The following prices are net F.O.B. Chicago and apply to both the diaphragm and the piston types.

Size, in.	Price	Size, in.	Price
$\frac{1}{2}$	\$23.50	2	\$35.00

Trucks That Have Proved Their Worth

The first Hyatt roller bearing trucks used by the B. F. Goodrich Company at Akron, went into service five years ago.

Since then they have bought many more.

The trucks are frequently loaded with 7000 pounds each and have been operated on an average of 16 hours daily—21 hours right now. In spite of this continuous hard service the repair costs have been absolutely nothing.

In addition to this advantage of durability, Hyatt bearings enable tractors to pull more trailers per train, eliminate storage battery strains, are easy to move by hand in making up trains and need only be lubricated three to four times a year.

Specify "Hyatt equipped" to your trailer manufacturer and have this dependable equipment working for you

A Summary of Expert Opinion

Roger W. Babson believes that "the new tariff bill reported to the Senate is looked on by most people as a highly bullish factor. Both this and the House bill carry higher rates on many things than have ever been in effect. Economists believe that in the long run such a tariff wall must be harmful to business, but there is no question that for a short while it will stimulate home production. Moreover, whether high tariff or low, it will be a great relief to get the matter settled. . . . Domestic manufacturers and producers should be encouraged by the outlook. The age-old tradition that high protection means good business never fails to stimulate confidence. The activities of the Government will continue distinctly pro-business. Even a soldiers' bonus, while unfavorable to business in the long run, would act as a temporary stimulant while the money was being spent. Appropriations for road building, freight rate reductions, encouragement by the Federal Reserve System and the optimistic attitude of every official department will all be concentrated toward making better business between now and fall."

The **United Business Service** points out that "It is rare that, following a period of severe depression, prosperity returns almost at one bound. . . . There are causes at work that could very well bring about a setback and a secondary depression before a real return to prosperity is accomplished. They are (1) Labor troubles. The deflation of labor is not yet completed, and labor difficulties act as a brake on progress. (2) Tariff agitation and the prospect of a tariff which, if enacted, will choke our foreign trade, prevent the payment of debts due from abroad, further depress the shipping industry. In our judgment it would be better for the country to let the tariff alone than to pass the pending bill. (3) Taxes, which must continue high for many years to come and act like a ball and chain on the feet of industry. (4) European conditions, which are not yet liquidated and may lead to another outbreak of war in Europe before the liquidation is accomplished."

"We believe, however, that the present improvement will last practically throughout 1922 and any approaching setback will cast its shadow far enough ahead to give adequate warning."

In the opinion of the **Harvard Economic Service**, "Greater optimism concerning the business outlook has recently become evident, as the nature of the improvement in business conditions is appearing more clearly. Despite such unfavorable factors as the late spring, floods, and the strikes in the coal and textile industries, the advance has been widespread. The expansion of building has stimulated

the demand for cement, paint, lumber, and other building materials. More hardware, agricultural implements, and automobiles are being purchased."

The **Department of Commerce**, in its **Survey of Current Business**, states that "Two outstanding features of more than ordinary importance are the marked increases in iron and steel activity and the big increase in construction. Since April 1 the coal strike has resulted in almost total cessation of work in the anthracite mines and a reduction of more than 66 per cent in bituminous output; however, owing to the exceptionally heavy stocks of coal, this situation has so far had little effect upon business."

George E. Roberts of the National City Bank of New York, says that "Trading in all lines is on a short order basis. Foreign buyers wish to avoid the risks of exchange fluctuations so far as possible, and in the domestic trade there is a prospect that in some lines, particularly clothing and textiles, prices may be lower. There is general agreement, however, that both at home and abroad stocks have been worked down to the minimum and that there must be constant buying to meet the demands for current consumption. This is one respect in which the situation is decidedly more favorable than it was in the latter part of 1920 and during most of 1921."

The **Brookmire Economic Service** believes that "A careful estimate of the amount of purchasing power which can be exerted by the various groups which constitute consuming demand alone affords some accurate basis of judgment as to the character, the time and extent of better business. Briefly, the ultimate buyer is included in one of five great groups. These are: (1) Building and construction operations. (2) Retail domestic trade. (3) Railroad and public utility buying. (4) Government buying. (5) Export trade. The full force of buying activity of all these groups is not necessary for a period of prosperity nor is the pressure of each group simultaneously exerted. In the periods of active business which have occurred since 1914, Government buying and export trade have been the dominating factors. In the short post-armistice prosperity railroad and public utility buying and construction operations were not active factors. At the present time the latter two are exerting the greatest pressure and it is the purchasing force of the construction field and the railroads that is giving the initial impetus to present business expansion."

The Fortnight

The Reported Oil Concessions

THE announcement that an agreement had been entered into between the Royal Dutch and Shell companies of England and the Soviet Government of Russia regarding the Baku and Azerbaijan oil concessions came as something of a bombshell to American oil interests.

The French delegates to the Genoa conference in particular, were frankly outspoken in their belief that the act amounted to commercial treachery on the part of England. The report was indignantly and emphatically denied by representatives of the English firms and by the official representatives of Soviet Russia. Nevertheless, a fairly well defined feeling exists that some such arrangement has been mutually agreed upon, if not actually entered into.

This means, if true, that the British concern has stolen a march on the Standard Oil Company. Whether the advantage will be a material one depends entirely on the extent of the concession and the possibility of further concessions to the American group.

Financial Progress at Genoa

LITTLE progress has otherwise been made at the conference at Genoa, except the adoption of a financial program which amounts to the appointment of a commission to readjust the reparations. J. P. Morgan is now in Europe attending the meetings of the financial commission. Versailles, Washington, Cannes, Genoa, next stop . . . ? . . . ?

Politics Delay the Tariff

THE tariff, like most other Congressional legislation affecting business, has been progressing at a snail's pace. A Treasury expert estimated that at the present rate of progress, the Fordney-McCumber measure would be passed by the Senate sometime during the afternoon of September twenty-ninth, 1946. Unless some of the political discussions which have held up the measure during the last fortnight can be done away with in the future, those experts who declared that the bill would go through before August first will have to revise their estimate.

Protection Instils Confidence

AT the same time, the mere fact that a tariff bill has been framed and that it is a high protective measure has given business men in general, that feeling of confidence, which always accompanies high tariff legislation. The feeling is not always justified, because too high a tariff eventually reacts to the disadvantage of the country, but temporarily, at least, its effect is favorable.

No Improvement This Summer

GENERAL business conditions throughout the country have not lived up to expectations. The tremendous boom in the building industry and the railroads' re-entrance into the commodity markets caused some improvement which led many to expect that prosperity was coming back with a rush. The gain was merely seasonal and did not amount to a great deal. The summer months will, in all probability show a decline and business will, according to the best information, pick up again during the fall and increase in volume through the winter. Retail spring sales for the country were much under the estimates made by many of our "Sunshine spreaders."

Steel Merger Hits a Snag

THE proposed amalgamation of several independent steel companies into a group which will contest the field with the United

The Battle Rages

(Kansas City Times)

States Steel Corporation is nothing new to those familiar with conditions in this industry. The merger has not yet gone through and it is reported that some of the officials involved do not feel that all the plants which would combine to form the new corporation are in physical condition which would warrant a pooling of interests. Developments along this line would indicate a readjustment of financing before the deal is completed.

Coal Pinch Being Felt

THE coal strike is beginning to make itself felt—on both sides. The steel industry, which is now producing at about seventy per cent of capacity, is becoming concerned with its supply and it is understood that were it not for the textile strike in New England, many mills there would have

in Perspective

felt the shortage as well. On the other hand the miners in the bituminous fields are feeling the pinch very sharply and emergency relief measures are being put into effect. Should the strike continue much longer Government interference appears inevitable.

Teapot Dome Lease

THE leasing of the Teapot Dome oil field to the Sinclair interests by the Department of the Interior caused a political flurry which may force Secretary Fall out of the Cabinet. The President has started an investigation into the matter and the affair may develop into a second Ballinger case.

On the other hand there is no evidence to the effect that the lease was not advantageous from the Government standpoint.

Rate Reduction Near

THE rate reduction which the Interstate Commerce Commission has been expected to announce has been delayed, but the reduction will be made in the near future, according to the best information. Basic heavy commodities will probably be favored, and there will be a reduction in coal rates amounting to ten per cent or more.

Big Month in Securities

THE month of April showed the heaviest volume of trading on the New York Stock Exchange in two years, and prices advanced rapidly on representative industrials and railway issues. Many shares rose to the highest point since the fall of 1920. During the first three weeks of April transactions on each full day were over a million shares. Sales of bonds during April were also unusually heavy. The flow of new foreign securities into this country was even heavier in April than in March. The four active liberty bond issues rose to par during the second week of April and caused an increased sale of Government securities.

Altogether, April was an unusual month in the financial district.

Spread Still Too Great

GENERALLY speaking, the spring gains in industry were entirely on the manufacturing side, and before distribution can improve in accordance with the gains in manufacture, the spread between wholesale and retail prices will have to narrow even more. Where this spread has been reduced to a minimum, business is moving very smoothly, as witness the automobile industry. In cases where the spread is still too great, as in the clothing industry, retail sales may still be expected to fall below normal volume.

Oil: Russia's Ace in the Hole

How the diplomatic game is being played with an eye to the world's oil supply, and how Soviet Russia is playing its cards

LITTLE by little the province of diplomacy is narrowing to the field of oil. The navies of the future, whether reduced in size or not, depend upon oil, submarines more wholly than ever did battleships. Behind France's position at Washington was an oily background. The invitation to Soviet Russia to be represented at the Genoa Conference was smoothed with oil. Last summer, in Tiflis, when Americans had to surrender their passports to enter the Socialist Soviet Republic of Georgia, I met a young American in the ante-chamber of the Commissar for Foreign Affairs of Georgia. He represented Standard Oil. In Moscow self-confident commissars were playing the game for the de facto recognition of the Soviet Government with an ace in the hole—and that ace is the second largest oil field in the world. It is located within the Russian Soviet Federation, and ever since the Armistice was signed in 1918, it has been the prize of intrigue, negotiation, war and international grand larceny. Whatever they may tell the public at conferences or in the press, in the back of the mind of every great power statesman today is oil.

Our Need for Oil

AND we, in the United States, are concerned, and well might be. Ours is the largest oil field in the world—60% of all the oil produced, at present at least, anywhere. But there are new fields whose full capacity is not yet known; and it is unlikely that we shall be able to hold the mastery of the world's oil situation very long. There are those who claim that at the present rate of production the American oil wells will be exhausted in 25 years. If so, oil is a very vital matter indeed to us.

Now the trouble is that most of the claims, so far as the known oil fields of the world are concerned, are already staked out. But there is a vast one which is not—the Russian field. And that is what the world is after now,

with all its backing and filling as to the terms upon which Russia will be readmitted to good international society.

The Greatest Oil Fields

THE second largest oil field in the world, the Russian oil district is not, technically speaking, within the confines of the Russian Socialist Federated Soviet Republic. The two principal oil areas are the Baku fields, on the Caspian Sea, in the Socialist Soviet Republic of Azerbaijan, allied to Soviet Russia but not part of it; and the Grosny fields, in the Autonomous Gorsk Republic, 60 miles west of the Caspian Sea and 50 miles north of the Caucasus mountains. The Baku field is the larger but the Grosny field is the newer; and while the Baku wells produced 72,801,116 barrels in 1916, and the Grosny wells less than a third this amount, the damage the Baku wells suffered during and since the war has greatly reduced their production, while production at Grosny is on the increase. However, these two, with several smaller neighboring fields, were good for over 10,000,000 tons of oil a year, even when badly developed under the old Russian system. It is plainly nothing to sneeze at.

Nor indeed has anybody sneezed at it; quite the contrary. When the sound of the last rifle shot died away on November 11, 1918, those with an eye to the future discerned three vast oil properties to be had for the getting, and one to be negotiated for. The three were in Mesopotamia, Persia and Russia, and the one that could not exactly be seized, because it was in an allied country, was in Rumania. Russia no longer counted as an ally, of course.

So far as Mesopotamia and Persia were concerned Great Britain had the inside track. Her armies were in both places, and that possession was nine points of the law, in any case. But the British firm known as the Turkish Petroleum Co. had had the foresight to lease from the Ottoman Government the

greater part of the Mesopotamian oil lands on June 28, 1914, and the Treaty of Sevres reviving that agreement, put British capital in undisputed control of the Mesopotamian oil field. In Persia, the British Government itself took a hand, and by the Anglo-Persian agreement of August 9, 1919—cleverly negotiated at the very moment that general peace terms were being discussed in Paris—secured for British interests in Persia a virtual monopoly of all development in that country, of which the Government-controlled Anglo-Persian Oil Co. profited to secure concessions covering the whole of Persia.

The British at Baku

ALL of this was done before one could say Jack Robinson. But matters did not move so smoothly in the former Russian oil territory around Baku. Not that the British lost any time getting in on the ground floor there, either. The German agents, who had made their way to Tiflis, in Georgia, in the summer of 1918 when the war seemed to be going their way, were scarcely out of one door of the Transcaucasian isthmus, between the Black and Caspian Seas, when the enterprising British were in at the other, at Baku. They arrived on November 17, 1918—six days after the Armistice had been signed on the west front, and their first act was to place a British control officer in charge of the oil wells, and to stretch a line of British Indian troops across the isthmus to Batum, the Black Sea outlet of the oil pipe line from Baku. And immediately, the British Black Sea fleet began to get its oil from the Baku fields.

But the game was not so easily won as at first appeared. Much blood had been shed in the struggle for the oil fields of Baku before ever the British arrived, and those who had shed the blood had no intention of letting go of their booty. Azerbaijan, of which Baku is the capital, is a Mohammedan country, and when the revolution of November 1917

Here Are the Stakes in the Great Diplomatic Game Now Being Played at Genoa. A View of the Immense Oil Wells at Bibi-Eibat, near Baku

Where the Oil Is Stored—the "Block City" at Baku. Storage Tanks That Hold the Richest Prize That Russia Dangles Before the Rest of the World

had thrown all Russia into confusion, the Mohammedans of Azerbaijan declared their independence of Russia and set up a Moslem state of their own, attacking and killing large numbers of the Russian soldiers, who had been fighting the Turks until the Treaty of Brest-Litovsk turned them loose, and who were making their way back to Russia across Azerbaijan, more as a mob than as an army.

"Off Agin' On Agin'"

THIS conduct scarcely pleased the Russians, and as some 50,000 workers in the oil fields of Baku were also Russians, the retreating Russian soldiers joined the Russian laborers and together they upset the infant Mohammedan "republic" and established a Soviet Government in Baku on the latest Russian lines, including the nationalization of the oil wells. Of course the Mohammedan owners of the oil lands could not see this at all. They had been used to receiving large royalties from the Russian, Scandanavian, Dutch, French and British lessors of the wells, and doing nothing for this providential income. When it was stopped, they appealed to their co-religionists, the Turks, to come and help them get back their land; and the Turks came.

For with the Turks there was another element in this complicated situation, and a vital one. Mohammedan Azerbaijan was a link in the chain of Moslem lands stretching from Thrace to India, and once this chain was forged, a vast Mohammedan Empire would have been created under Turkish leadership, almost as glorious as that Mohammedan Empire the Arabs had built up in the VIII Century. It was with this vision that the Turks had joined the Germans in the war; and now with the break-up of Russia, it looked possible of realization. Oil was nothing to the Turks; but the Empire was. So they came to Baku, and turned on the Soviet Government, which the Russian workman of the oil fields had set up, and an anti-Bolshevist Mohammedan government took its place.

But with the Turks, came the Germans, who took over the oil fields for their own use; and the oil land owners

found themselves no better off than before. So they promptly appealed to the British forces in Persia to do for them what the Turks had failed to accomplish; and so soon as the Armistice on the west front gave the British freedom of action, they came, in their turn.

In order to secure a firm hold on the immensely rich prize that had fallen into the lap of Great Britain, in this way, something had to be done to prevent Soviet Russia, no longer in a state of chaos, but with a growing and a formidable army, from sweeping down along the Caspian and reconquering a source of over a million tons of illuminating oil and twice as much fuel oil per year. It was with this in view that, in 1919, the British supported Denikin's anti-Bolshevist army with money, war materials and military advisers; for Denikin stood between Soviet Russia and British control of the Baku oil fields.

Buying Oil Stocks—On Paper

FINANCIALY, also, the British interests became active in buying up both local and foreign owned stock in oil companies for sale for a song on account of disturbed conditions in the Baku region, and the long period which had intervened since any dividends had been forthcoming. I was told in Baku in 1919 when the British were in control of the oil output, that any export of oil except for the use of the British fleet was forbidden for the purpose of driving the price of stock still lower, that it might be bought in the more cheaply. In December, 1919, every oil reservoir in Baku and along the pipe line to Batum was full to overflowing and the owners of oil storage tanks were asking more to store the oil than it would fetch in the market.

Under the circumstances the oil land owners who had welcomed the British the year before were no better off than they had been before the British came, and the 50,000 Russian workmen in the oil fields were distinctly worse off. There was no work for them. So when Denikin's army collapsed, Azerbaijan once more turned into a Soviet republic and the British left Baku so hurriedly that several oil control officers remained prisoners of the new government.

The British did not give up, however. The moment was propitious to secure control of the outstanding shares of oil stock, seemingly not worth the paper they were printed on. On May 4, to the 31,000,000 pounds invested in the Caucasian oil industry, British capital added an all-British control of the Royal Shell Transport and Trading Co., originally a Dutch concern. The French Rothschild oil interests, representing some \$55,000,000 in stock in the Royal Shell Co., were, in the phrase of Senator Beranger, of France, "driven to seek British protection and to unite with England in the exploitation of the oil resources of Mesopotamia and Persia." The terms upon which this union was laid down, at San Remo, on April 24, 1920; 75% for British and 25% for French oil interests. The Sykes-Picot agreement of 1916, by which France had hoped to receive the upper Mesopotamian oil fields around Mosul, went into the discard. The French had been frozen out in Mesopotamia. The British controlled in Persia. On July 28, 1920, the Royal Shell Co., now British, secured \$250,000,000 worth of oil properties at Baku from discouraged Russian shareholders who could no longer hold on. On paper, at least, the British thus also controlled the Baku field, and by the San Remo understanding dominated French oil interests even in Rumania.

Britain Still In Game

SO far as Mesopotamia was concerned, the British monopoly of the entire Near Eastern oil field was real enough; but with respect to Persia it was still largely on paper, while in Baku it was entirely so. For on July 15, 1920, the British had been forced to leave Transcaucasia altogether, and the investments in Baku oil stock made after this period were for future reference. For Soviet Russia controlled in Baku and Grosny as well, and what output there was from both oil fields went to Russia, not abroad. And it is that way still.

But the British oil interests, which worked so untiringly for almost two years to gain possession of the second largest oil fields in the world, have no intention whatever of giving up. Not only

(Turn to page 966)

The Race for the Russian Market

European countries are steadily increasing their trade with Soviet Russia—Is the United States to be left out of one of the world's greatest markets?

TO the Manufacturers of the World:

Please deliver during the next ten years, and charge to our account, iron and steel products, heavy chemicals, paper and textiles to the value of \$300,000,000 a year. Start shipping the goods as promptly as possible, because we will have to shut down our plants if we don't get them soon. Payment will be made chiefly in the produce of our grain fields and oil wells, which are among the richest in the world.

(Signed) RUSSIA.

* * * *

THIS is the order which Russia would like to place in the world's market for manufactured goods. She wants to trade with the world; and the world, although it is a little afraid to take the first steps, would like to trade with her.

The question for the business men of the United States to consider is this: How can we get our share of this Russian trade?

The politicians of the world are gathered at Genoa, trying to find, among other things, a basis for the opening up of Russia to world commerce. They haven't advanced far toward their goal, but the business men of the world, who have been hovering around the conference, have not let the impotence of the politicians tie their hands entirely. On May 1 there came from Genoa news of a business event that far overshadowed the reports of the political bickerings of the day. It was announced that Russia had signed an agreement for the development of her oil fields by foreign capital.

According to this agreement, the Russian wells, including those of Baku, will be exploited by the British Shell group of oil companies, including the Anglo-Persian and the Royal Dutch corporations. If the signing of this contract is a fact, instead of a rumor, it is a defeat for American interests. The Standard Oil Co., personally represented by

A. C. Bedford, went to Europe to secure oil concessions.

American business men would do well to study this agreement as an example of the sort of contract the Soviets will make. Its terms, as cabled to *The New York World* by Samuel Spewack, are as follows:

The sale of all mineral oil in the Russian fields is confined to a syndicate, the capital of which will be furnished half by the Russians and half by the Shell group. The syndicate will issue securities in order to make possible the distribution of the product.

The syndicate will get 5 percent of the selling prices for quantities down to 100,000 tons. Varying tariffs on smaller quantities are arranged. After deduction of general expenses and interest on the syndicate's obligations, the profits will be divided equally between the Russian Government and the Shell interests.

The agreement is to run for five years. After that the Russians have the option to purchase the interest of the Shell group in the syndicate or renew the convention for another five years.

It is stipulated that direct sales to other governments must not exceed 50 percent of the production destined for export. The Russian Government will guarantee with the existing stock of oil

the syndicate's investment which is necessary to organize oil transportation from the wells to the seaports. The Russians also guarantee the interest on the securities which the syndicate will issue to finance the transportation of the oil.

The syndicate is permitted by the contract to call in foreign labor and conduct the business according to its own judgment. But the number of foreigners must not exceed 50 per cent of the total personnel.

The enterprise is to be guided by the decrees and laws of the Soviet Republic. Especial emphasis is laid on the proviso that the workers must be employed and maintained under the Soviet laws. In other respects the managers will be free to conduct the enterprise as they please.

That any such contract has been made between the Shell interests and the Soviet Government was denied at Genoa, both by the Russian delegation and by Colonel J. W. Boyle, representing the Royal Dutch and Shell interests. It is quite possible that the report is true nevertheless, although the time may not be ripe for announcement, and it is also possible that the Russians are good enough traders to start such a rumor in order to spur up competition and get better prices. It is readily admitted that the Russian delegation has been negotiating with British and other interests for the output of the Baku and Azerbaijan fields. But whether the information is correct or not it is obvious that some such arrangement must shortly be entered into, either with British or American interests, despite French and Belgian opposition.

In spite of the fact that the American State Department does not consider it expedient to recognize the Russian Government, Americans are not wholly unable to trade with Russia. In 1921 the International Harvester Co. actually sold Russia \$1,600,000 worth of farm implements. Nearly 16 percent of Russia's total imports last year came from this country.

Trade Opportunities in Russia

An analysis of the Russian foreign trade situation from the viewpoint of the American manufacturer

THE World War, followed closely by the 1917 revolution and by a civil war immediately after, disorganized to a large extent the apparatus of almost every branch of Russia's industries, internal and foreign trade, and her economic life in general. Conservative estimates have it, and the latest available statistics indicate, that the present production of essential commodities in Russia is exceedingly low—about $\frac{1}{5}$ to $\frac{1}{4}$ of the pre-war normal. In some cases, production has fallen even below these figures. During the past three years the decline of industry has been nothing less than tragic. The facts in one case only, the metallurgical industry, are sufficient to prove this. The official report of the Supreme Council of National Economy to the Eighth All-Russian Congress of Soviets in December, 1920, described the situation as catastrophic. It is true that in Europe the metal industry has been rapidly decreasing, but in no country except Russia has the decline assumed such alarming proportions, as the following table of iron and steel production shows:

	Thousands of Tons		
	1913	1919	1920
Germany	64,476	45,148
Belgium	2,667	1,213
Russia	3,148	86

This is an output of 1920 compared with that of 1913 of 70% for Germany, 45.4% for Belgium, 2.7% for Russia.

Such marked decrease and inefficiency of production in practically every important industry in Russia are attributed

chiefly to complete lack of fuel, machinery, appliances, food, which lack is due to the natural results of war and revolution. This industrial and trade deterioration has led Russia to adopt a new economic policy, which with the acceptance of capital as a ground of economic recovery, the solution to certain pressing problems appears.

The great problem which faces Soviet Russia to-day is industrial re-establishment. Concessions and electrification, two of the predominating questions in Russia to-day, are the main roads for its speedy attainment. The questions are closely related. They are indeed the outcome of the new economic policy which rests economic recovery on two grounds, capital and engineering. The first admits of the exploitation by foreign capitalists of extensive hitherto unexplored areas; the second implies the electrification of the country on lines similar to those of Germany, America and Sweden, with the consequent development of a large engineering industry.

The new economic policy of the Russian Soviet Government has thus cleared the way for sound industrial and financial considerations of the problems of Russian national economy, of which the questions concerning foreign trade are receiving most attention. While at the outset it must be remembered that the economic life of Russia is undergoing alterations, and that the organization of the Government industrial and economic institutions, in particular, is in an experimental and fluid stage, there now is, nevertheless, a trading apparatus with

which it is possible to conduct ordinary, everyday business and trade. This trading apparatus consists of governmental co-operative and private agencies with responsible representatives in and out of Russia ready for foreign trade transactions.

Russia's Needs and Trade Opportunities

RUSSIA'S needs are enormous. Her financial situation affords no grounds for apprehension. Every indication seems to warrant that the economic development of the country has already begun and will proceed on a huge scale. Russia needs to buy billions of dollars' worth of goods with which to set her own hands producing. Her natural resources, the colossal wealth of which has become proverbial throughout the world, will amply suffice to put the country on her feet again; but the most elementary tools and materials are required to set the wheels of production in motion.

According to an American Commission, studying the Russian famine and agricultural conditions, recently reported that Russia is in need of \$500,000,000 worth of agricultural machinery and implements. But an insignificant portion of this huge business order has thus far been got hold of by American concerns. During the year 1921, the International Harvester Company has succeeded in selling to Russia \$1,600,000 worth of agricultural machinery and implements.

According to the "Plan for the Electrification of Soviet Russia," an official Russian Government report, Russia will

Course of Russia's Foreign Trade, 1904-1916

have to import, during the next ten years, a great many heavy industrial products essential to her immediate vast rebuilding program. It is estimated that the average annual imports into Russia for this period, consisting of iron and steel products, heavy chemicals and paper and textiles (raw, semi-finished and finished), would alone amount in value to upward of \$300,000,000. Russia will be obliged to import many of her industrial requirements, even though she can produce them more profitably at home.

Russia offers other big opportunities to Americans, not only in the concessions on natural resources with which Americans are now somewhat acquainted, but in the direction of establishing industrial plants for the manufacture of much-needed goods, which must now, and for a long time to come, be imported.

American capital, executive talent and machinery could well be employed in rehabilitating the following factories in Russia: Locomotive and freight-car shops, metal foundries, agricultural machinery, rubber goods, shoes, sugar, cement, lumber, leather articles, matches, paper, preserved fruits, furniture, textiles, wood-distillation products, sulphuric acid, and other heavy chemicals. In most cases, the Russian factories are not adequately equipped, lacking machinery and appliances, consistent with the latest engineering practices in this country.

What Russia needs in the rebuilding of her national economy, Germany and the other principal European nations are not in a position to supply. Germany might send her capable technicians and industrial organizers, but the main body of capital for Russian reconstruction will eventually have to come from the United States, the greatest creditor nation, although European middlemen are scheming to have this capital pass through their hands instead of direct to Russia.

Europe and the United States will severely compete for Russia's foreign trade. From the estimated volume and value of her import needs, the opportunities for selling to and buying from Russia are so unlimited that the scramble among the different nations to get the bulk of this foreign market promises to be excitable. That nation will win out which is best equipped with capital and modern foreign trade technique, readily applicable to Russian conditions.

Russia's Foreign Trade

BY way of emphasizing these opportunities for Russia's foreign trade to American manufacturers and exporters, and the methods to be pursued to secure to themselves a predominating position, the following analysis of Russia's foreign trade in the past, and the rôle played and to be played by the United States, is made.

For several decades prior to the World War, Russia had shown remarkable progress in her economic life, despite the fact that the country faced many obstacles, almost insuperable, from the formed bureaucratic Czarist régime. Along with this development of her national economy and internal trade came about also a very rapid expansion of Russia's foreign trade. In the course of the past generation, Russia has been assuming an increasingly important part in the world's trade, so much so that the present shattered foreign market is in part a result of the unbalancing caused by Russia's withdrawal from it. Tabulating in periods of 25 years, the following annual averages are arrived at (in millions of dollars):

Year	Export	Import	Total	Increase on the First 25 Years
1800-'24	32	24	56	100
1825-'49	56	50	106	189
1850-'74	131	132	263	467
1875-'99	298	248	546	972
1900-1913	574	472	1046	1765

The chart at top of page shows Russia's foreign trade during the last decade

preceding the war, ending in 1913, which was the last complete year unaffected by European conflict. The influence of the war upon the foreign trade of Russia is also shown.

Thus the beginning of the 20th century indicates the most intensive growth of Russia's foreign trade. The peak was reached in 1913, when Russian exports amounted to \$760,000,000, imports to \$687,000,000 and the total foreign trade volume amounted to \$1,447,000,000. These are very significant figures.

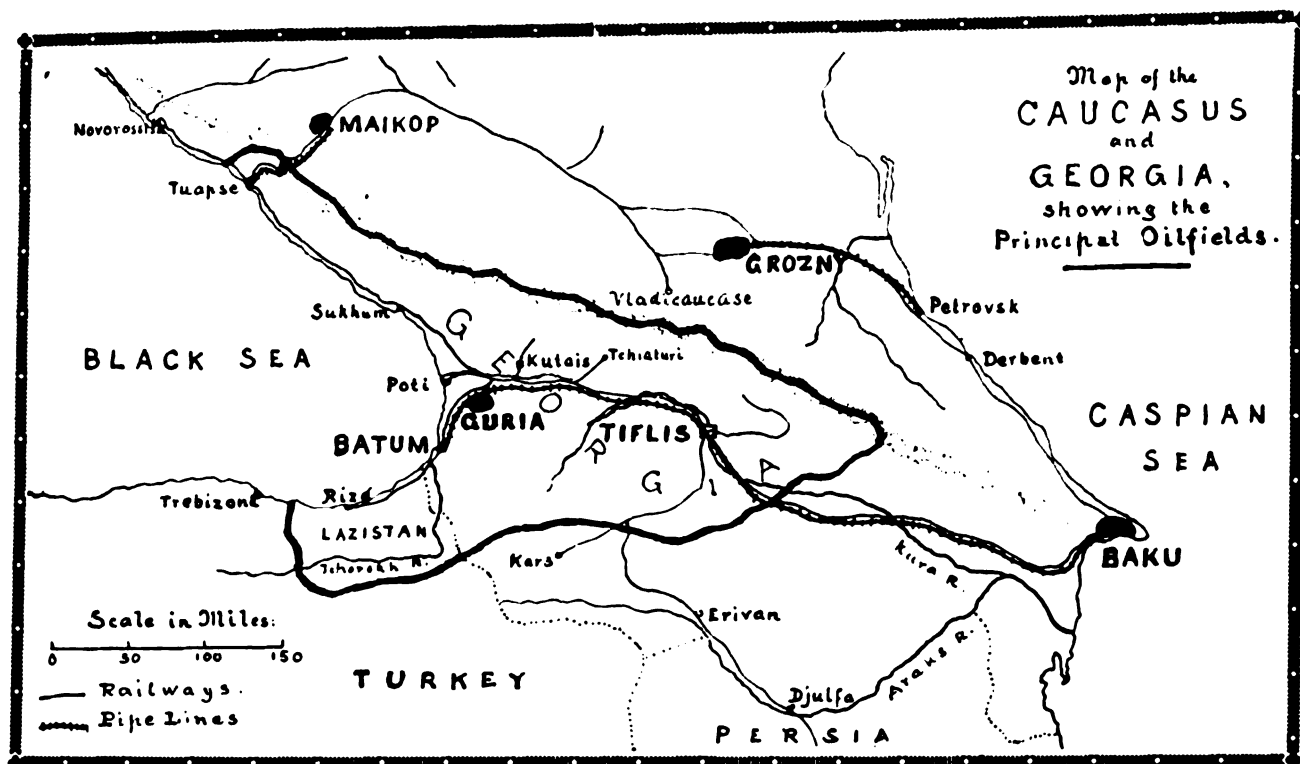

At the beginning of the 20th century, raw materials constituted the bulk of Russian exports, but during the period of 1913 to 1918, foodstuffs, chiefly grain, occupied the first place. The principal imports for the same period were raw materials and partly manufactured goods, and after these, finished products.

Germany Controlled the Russian Markets

THE relative participation of different countries in their foreign trade with Russia, at the beginning of the 20th century, is shown in the following table:

	1908-1913		1913	
	Millions of Dollars	Per Cent	Millions of Dollars	Per Cent
Germany	418	34.2	553	38.2
United Kingdom ..	219	17.9	220	15.2
Holland	91	7.4	99	6.9
France	70	5.7	79	5.4
China	53	4.3	58	3.9
Austria-Hungary ..	46	3.7	50	3.5
United States	46	3.7	47	3.2
Italy	35	2.9	45	3.1

The above table indicates quite clearly the domineering position held by Germany in the foreign trade of Russia. Germany controlled more than $\frac{1}{3}$ of Russia's foreign trade. In 1913, Germany absorbed 53% of the total imports of the country. England, which in the middle of the 19th century occupied the first place in trading with Russia, had been ousted from that coveted position and replaced by Germany, having been shoved into the second place by her.

Location of the Principal Russian Oils Over Which the Genoa Conferees Are Contending

Russia's Foreign Trade in 1921

RETURNS* are now available for Russia's import and export operations during the whole of the year 1921.

Britain and Germany together supplied 60% of Russia's imports.

From Germany the articles primarily intended for the restoration of Russia's industry and agriculture comprised

United States and Russia

IN 1913 the seventh place, according to table No. 1, was occupied by the United States, whose share of foreign trade with Russia amounted to only 3.2% of the total. If exports and imports for that year are considered separately, then the United States ranked thirteenth on the list of nations to which Russia exported goods and fourth among the countries from which Russian imports were drawn. This fact is particularly important when we consider that the comparatively small amount of direct business done, before the war, between the United States and Russia was due primarily to Germany's position as a middleman between Russia and America.

Russia's foreign trade with the United States has developed as shown in Table III.

In 1918 United States trade with Russia took a sudden sharp decline on account of the disturbed conditions engendered by the revolution in the latter country. The above statistics indicate the great drop in America's foreign trade with Russia in 1918, rise in 1919 to \$92,000,000, and then again a decline and an approach to the pre-war status.

Exports to Russia from the United States in 1913 included agricultural machinery and implements to the amount

TABLE II

Category	Weight in Thousands of Tons	Weight Per Cent of Total Imports	Value in Thousands of Dollars	Value Per Cent of Total Imports
Foodstuffs	334	36.3	16,061	12.9
Animal products	11	1.2	39,605	31.9
Timber and seed	13	1.4	504	0.4
Earthenware	1	0.1	227	0.2
Fuel, pitch, etc.	273	29.6	2,786	2.2
Chemicals	10	1.1	2,032	1.6
Metal, ores, machinery, tools	185	20.3	29,184	23.5
Paper and paper goods	30	3.3	3,977	3.2
Textiles	10	1.1	15,206	12.2
Wearing apparel, stationery, etc.	1	0.1	13,132	10.6
Miscellaneous (including famine aid 48,000 tons)	52	5.6	1,567	1.3
Total	920	100.0	124,281	100.0

The total imports for the year were approximately 920,000 tons and the total exports 205,000 tons, the exports being only 22% of the imports. Table No. II is an analysis of the categories of goods during the year, their value and the percentages of weight and price to the total imports.

As to the sources of origin of Russia's imports, Great Britain throughout the period was the chief market for the purchase of Russian imports and her importance increased with the growth of trade. Germany was the market of second importance and the U. S. third, as the following table shows:

	Per Cent of Total Imports
Great Britain	35.2
Germany	24.0
United States	15.8

Norway and Sweden are next in importance as the source of imports—10.1%—and the Baltic states next. Great

91.8% of the total imports, whereas articles imported from Great Britain for the same purpose comprised 36.6% of the total imports from this source. From this it appears that Germany has reassumed her pre-war rôle as the main supplier of Russia's requirements in tools and machinery.

The growth of imports throughout the year from the U. S. was slight, and relative to other countries her importance as a source of supply decreased. The bulk of the imports consisted of

Selling the Dominion Market with U. S. Goods "Made in Canada"

An analysis of the factors responsible for the location of factories across the border—many inducements offered to U. S. capital

PROBABLY no country involved in the maelstrom of the Great War made such rapid rehabilitation and extricated herself so speedily from the entanglements of the aftermath as did Canada.

Canada was not satisfied to achieve readjustment to the position she had occupied before the war. Canada is now, in a degree, previously unreached, a serious trading nation, and this means more serious competition for manufacturers in the United States who sell the Canadian market. It also offers an unusual opportunity for United States capital to invest in Canadian industry. United States investments for Canadian industry have never been greater than at present, the most noticeable feature being the large increase in the establishment of branch factories and plants of parent houses across the line.

When the British Held Control

PREVIOUS to the war the money which oiled the machinery of Canada was overwhelmingly British. English investment, of course, practically came to a standstill with the outbreak of the war, and post-war conditions of various natures all militated against the British investor sending his money to Canada. Funds were needed at home, with a purchasing power very much diminished, and British currency was at a very high discount in Canada, which was sufficient discouragement in itself against sending money overseas for investment.

The situation remains very much the same today. Though

some British capital is finding its way to the financing of Canadian industry, the general trend of economic affairs does not seem favorable to increased investment from that source.

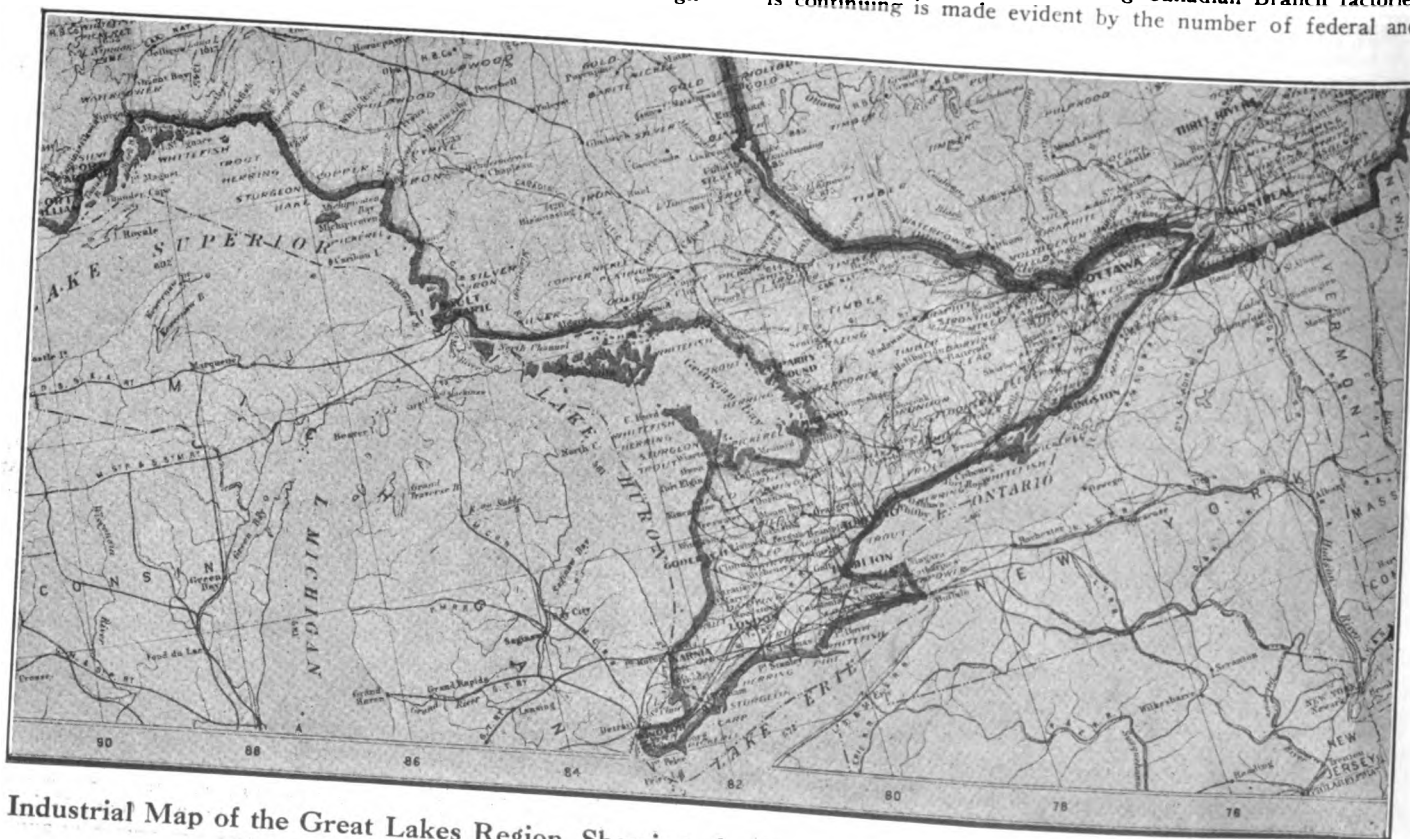

The precise situation that has worked against British capital has served to favor that of the United States. American money has been, and is, at a considerable premium in Canada, which is a sufficient inducement for anyone contemplating investment in the Northern field to act quickly.

So far as United States manufacturers are concerned, there is a further one in the "Made in Canada" campaign, which is now an enthusiastic economic movement from coast to coast in Canada. Householders look askance at the idea of purchasing where their dollar is discounted several cents, and are by every possible means curtailing their purchases across the border. This has driven United States manufacturers who are awake to selling in Canada, to establish plants there if they are at all keen about holding and developing their trade relations in the Dominion.

U. S. Branches in Canada

AS a result of a realization of these conditions among United States manufacturers more than 200 branch factories of their industries located in Canada in 1919, while a greater number made the move in 1920, there now being more than 700 such branch factories in Canada at the present writing, with some 200 others seeking locations.

That this process of establishing Canadian Branch factories is continuing is made evident by the number of federal and

provincial incorporations and the continuous stream of inquiries from the United States received by the various Boards of Trade and other industrial bodies concerned in assisting and placing new industries. These inquiries cover every branch of manufacturing activity and in one Ontario town more than 100 such inquiries were received last year from a wide variety of manufacturers.

What induces so many United States manufacturers to locate in Canada?

The reasons are simple. Prior to the war, when there were only some 350 branch plants of United States industries operating in Canada, it was generally accepted that they had made this move to escape the Canadian tariff, and this was probably correct in the majority of cases. But now the wide-awake United States manufacturer is actuated to this end by the conviction that he can manufacture for the Canadian market far more profitably in Canada than in the parent plant.

United States firms have also discovered that export orders received by the parent company in the United States for shipment to the United Kingdom and other parts of the British Empire can be handled with greater facility and more expeditiously through a branch house manufacturing in Canada. In the matter of Empire trade, United States firms are induced to the same end by the opportunity afforded them of securing the advantages of the many preferential tariffs which exist under "most favored nation" clauses for the benefit of the countries within the British Empire.

Preferential Treatment

PREFERENTIAL treatment is accorded, for instance, certain Canadian goods by Great Britain, New Zealand, South Africa, Australia, British Guiana, and West India Islands, while under the terms of an agreement with France existing since 1907, Canada's products enter that country under especially favorable conditions. Again, the United States firm which has developed a market for its products in Canada, has its market within easy reach and is in a position to expand with the domestic market as well as the export trade.

Canada is naturally anxious to have her industries developed and capital from the United States is as welcome as capital from England. The increased population which such industries encourage increases the market for all goods sold in the Dominion.

Canada possesses all the requirements for sound industrial expansion, lacking only the necessary capital. Therefore, Canada through organizations of every nature, its railways, its incorporated cities and towns, its civic bodies and boards of trade, offers every inducement to new industries to locate there. In no country is greater encouragement given to foreign manufacturers to locate, while the expanding domestic market and the rapidly growing export trade furnish a sure and steady output for products.

In some of the Canadian provinces certain towns still offer a bonus to new industries locating within their confines, though in other provinces this practice is forbidden by law. There is, however, sufficient inducement without this. A great many towns of substance and progress, anxious to expand industrially, offer free sites to new manufacturers, and in a number of localities exemption from taxation is granted for varying periods up to 20 years from the date of location. Water is often provided at cost to industry, while some cities and towns make themselves responsible for the expense incurred in the installation of public improvements in the way of street extensions, sewerage, waterworks, etc., about the site and premises of the incoming industry.

A striking and important feature regarding Canadian industrial development is that the country possesses an enormous wealth of water power, approximately 19,500,000 horsepower widely distributed. The insignificant portion thus far developed provides light, heat and power to industries at very low rates, special terms being generally accorded over the low cost of generation and production. Winnipeg, for example, provides power to industrial concerns at a rate cheaper than any other point on the American continent.

New industries locating in Canada do so at a minimum of expense. Boards of trade and industrial commissioners

(Turn to page 972)

The Danger in Tax-Exempt Bonds

Tax-free securities divert funds from legitimate industrial channels and thus delay or prevent business development

A LARGE Eastern corporation put through an important piece of financing last month with enviable success. It sold an issue of \$45,000,000 fifty-year bonds, bearing 4½ per cent interest, to a syndicate of New York bankers at 102.766, netting the corporation a premium of \$1,244,700. In other words, the corporation easily got its money at 4.11 per cent.

Officers of corporations that are accustomed to pay a great deal more than 4.11 per cent for their money these days may believe that this is a fairy story. It is not. In spite of the fact that high-grade investment bonds are now selling at prices to yield 5 to 6 per cent, and that many good bonds yield even more, this particular 4½ per cent issue was oversubscribed eight times. What's the explanation?

Simply this: The borrowing corporation in this case is the City of New York, and its bonds are free from all Federal income taxes and all State levies. This exemption enables the city to borrow at an interest rate nearly one point cheaper than that which is paid by other corporations whose securities—underlying railway bonds, for instance—appear equally attractive in other respects.

Unfair Competition

THE sale of these city bonds at a record premium brings before the business world with renewed force the fact that business enterprise is handicapped by the necessity of competing in the money market with tax-free securities. Big investors tend more and more to put their money in exempt bonds, with the result that this capital is lost to industry, and businesses are forced to pay higher interest rates for the money they need for permanent financing.

The attractiveness to large investors of the tax-free feature is demonstrated by the following table of the actual returns to persons of various incomes that are yielded by tax-exempt bonds bearing 4 per cent interest:

To an investor whose income is \$6,000 to \$10,000, the return is 4.40%

To an investor whose income is \$18,000 to \$20,000, the return is 4.65%

To an investor whose income is \$28,000 to \$30,000, the return is 5.00%

To an investor whose income is \$40,000 to \$42,000, the return is 5.40%

To an investor whose income is \$50,000 to \$52,000, the return is 5.80%

To an investor whose income is \$60,000 to \$62,000, the return is 6.25%

To an investor whose income is \$70,000 to \$72,000, the return is 6.78%

To an investor whose income is \$80,000 to \$82,000, the return is 7.40%

To an investor whose income is \$90,000 to \$92,000, the return is 8.16%

To an investor whose income is \$100,000 to \$150,000, the return is 9.10%

To an investor whose income is over \$200,000, the return is 9.53%

In view of these facts, large investors will of course turn to tax-exempt bonds, leaving the railroad and industrial issues to the smaller fry, who will get higher rates of interest than they would otherwise receive.

\$10,000,000,000 in Tax-Free Bonds

IT is estimated that there are about \$10,660,000,000 totally or partly tax-free bonds outstanding today. These are Liberty bonds and Victory notes, bonds of the War Finance Corporation and of Federal Farm Loan Banks, obligations of the United States issued before September 1, 1917, and bonds of the States, territories, municipalities and the District of Columbia. It is impossible to say what percentage of the total outstanding investment bonds of all kinds these tax-free issues constitute, because that total cannot be estimated with any degree of accuracy. Income taxes were paid in 1918 on the interest on about \$30,000,000,000 of bonds, but this figure

cannot be accepted as approximating the total held by American investors because it does not include holdings of corporations nor of individuals with incomes so small that they do not have to file reports. But whatever the total, the \$10,660,000,000 of tax-free bonds is large enough to form a substantial proportion and to make a considerable difference in the market for investment funds.

When a government issues tax-free bonds it creates an easy market for its securities. This is, of course, the reason why Congress made the Liberty bonds tax-exempt. This attractive feature gave the bonds an advantage over other securities. This advantage was necessary in time of stress. Farm loan bonds are exempted for a slightly different reason. Exemption for these securities makes it possible for the farmer to borrow money on his land at a lower rate of interest than would otherwise be possible.

It is further argued in favor of tax exemption that this prac-

(Los Angeles Times)

The Best Time to Advertise

Advertising men agree that advertising stimulus is most needed in times of depression, yet figures do not indicate that business men "take their medicine" at this critical time

ADVERTISING is a stimulus to business. It increases demand, and moves goods that would otherwise lie in warehouses. This is a truth that is pretty universally recognized, but how universally is it acted upon? Do business men increase their advertising when trade gets slack, so that the stimulus of the printed word may act in opposition to the sluggishness of the buyers?

Advertising men will answer that business men do nothing of the kind. On the contrary, they say, the average industrial executive spends less for publicity when buying is slow than when trade is active, in spite of the fact that he knows advertising will help to keep things moving.

Interesting information on this subject may be gathered by a comparison of statistics. *Printers' Ink* has compiled figures showing the total amount of advertising, in dollars, printed every month for four years in 61 magazines, including all the important national, class and women's periodicals. The Harvard Bureau of Economic Research publishes a monthly index of the business activity of the nation. If these two sets of figures are arranged in charts and compared, the observer will be able to see whether, when business gets slow, advertising is permitted to slump also.

The *Printers' Ink* figures are as follows:

	1918	1919	1920	1921
January	1,086,355	1,095,476	1,888,490	1,408,114
February	1,249,937	1,483,198	2,230,165	1,478,314
March	1,584,595	1,986,233	2,607,249	1,609,095
April	1,635,508	2,128,709	2,770,092	1,730,431
May	1,602,090	2,337,322	2,917,431	1,640,439
June	1,462,081	2,019,475	2,507,385	1,542,865
July	1,092,669	1,639,710	1,924,190	1,179,234
August	1,054,167	1,680,484	1,861,219	1,047,982
September	1,300,516	2,057,326	2,353,319	1,354,635
October	1,455,091	2,324,355	2,649,089	1,558,786
November	1,476,448	2,380,664	2,398,028	1,461,295
December	1,283,982	2,221,832	2,123,795	1,385,273

These statistics are graphically presented in the chart at the bottom of this page.

A complete comparison with the Harvard index is not possible, for the Harvard records are available only since the armistice. This index, unlike the *Printers' Ink* figures, shows fluctuations merely, and gives no indication of the actual volume of business done. It is not a statement in dollars, or pounds, or any other unit representing objective things; it is an index, made up by compiling a weighted average of the bank clearings outside of New York, Bradstreet's index of commodity prices, the United States Bureau of Labor's price index, Bradstreet's records of business failures, imports of the United States, pig-iron production and the unfilled orders of the United States Steel Corporation. The composite of all these figures, which is a fairly reliable indication of business conditions, fluctuated as follows:

	1918	1919	1920	1921
January	0.85	4.25	—3.80
February	0.00	3.85	—4.50
March	0.12	4.80	—4.50
April	0.10	4.50	—5.35
May	1.00	3.75	—5.60
June	1.75	3.60	—5.50
July	2.75	3.15	—5.55
August	3.25	2.50	—5.10
September	3.75	1.75	—5.05
October	3.50	0.50	—5.25
November	1.37	3.25	—1.50	—5.35
December	1.25	3.40	—2.50	—5.35

Statistical Proof

THE figures show that advertising did not drop for some months after the decline of trade. The height of business activity was reached in March, 1920. That was a good month for advertising, too, but the succeeding months were even better. The largest volume of advertising in the entire four-year period was done in May, 1920, two months after the decline in business had begun.

After that, advertising dropped for its regular summer slack season, but in spite of the fact that business was declining

How Can Railroads Improve Service?

The efficiency of railway labor is the crux of the problem—how it can be improved—possible effects of failure to reduce rates

IS it possible to develop the railroads of the United States so that they will give truly efficient service to business? What should be done to help the roads attain a state of maximum efficiency? These questions, which affect industry in one of its most vital spots, were discussed last month at the semi-annual meeting in New York at the Academy of Political Science. Among the speakers were Henry Wallace, Secretary of Agriculture; Daniel Willard, president of the Baltimore & Ohio Railroad; W. N. Doak, vice-president of the Brotherhood of Railway Trainmen, and William J. Cunningham, professor of transportation of Harvard University.

The consensus of opinion was that the Transportation Act of 1920, under which the railways are now operating, provides a fairly satisfactory basis for the development of efficiency. A fair trial has not yet been given to the act, it was said, and the nation should go ahead along the lines provided in the act, in the expectation that the outcome will be successful.

An Economist's Opinion

PROFESSOR CUNNINGHAM, discussing the topic, *How the Railroads May Render Maximum Service*, said:

"With the passage of the Transportation Act and its constructive rule of rate-making, as well as its recognition of the principle that carriers are entitled to a fair rate of return on property value, and with the rate increases authorized in 1920 by the Interstate Commerce Commission with a view of producing a net return of 6 per cent, it was hoped that substantial progress had been made toward the solution of the financial problem. All calculations, however, were upset by the business depression. Yet it is not proper to interpret the disappointing results in 1921 as an indication that the Transportation Act has failed. Its real test must await a return to normal business conditions. My own opinion is that its inherent soundness will then be demonstrated.

"In the meantime how are the railroads to render maximum service? It seems to me that the answer is:

1. By improvement in management;
2. By better relations with labor; and
3. By patience and tolerance on the part of the public.

"Without intelligent management, loyal service from employees, and the support of public confidence, satisfactory and economical service is impossible. In whatever degree an improvement is brought about in any one or in all of the three fields, in that degree will progress be made toward the attainment of the objective named in the subject of this paper.

"The Transportation Act of that year marked a new era in which the regulating authorities are charged with new responsibility for the powers which they may wield. Prior to 1920 the spirit of regulation was mainly corrective and punitive. The new law, while continuing the powers of

"PUBLIC patience and tolerance are necessary before the railroads can render maximum service."

"It would be a mistake for Congress to pass a law prohibiting strikes unless we are quite certain that we shall be able to enforce such a law once it has been enacted."

"Wage standards and levels should be established independent of and separate from transportation rates."

"Our present high railroad rates cannot be continued without disaster to the railroads themselves. Rates must come down to a point not far above pre-war levels."

—From discussion by the Academy of Political Science.

correction and punishment, also recognizes the fact that the prosperity of railroads is essential to satisfactory public service, and it directs the regulating bodies to exercise their authority so that consideration shall be given, among other things, to the transportation needs of the country and the necessity of enlarging transportation facilities 'in order to provide the people of the United States with adequate transportation.'"

What a Railway President Thinks

PRESIDENT WILLARD, of the Baltimore & Ohio Railroad, said he believed that the Transportation Act of 1920 provided "a workable basis for the future successful operation of the railroads of the United States, in harmony with our long-established policy of private ownership and operation.

"I firmly believe," he added, "that if the act is permitted to remain as it is for a period of five years, and if the railway managers could be assured that it would not be changed within that period of time, that such knowledge would have a most stimulating and encouraging effect, not only upon the railway managers, but upon investors as well, and would in itself go far to assure the success of the act."

Mr. Willard praised the provisions of the law relating to the return allowed on capital invested in the roads.

"It is essential in the public interest that all the roads, generally speaking, should be able to survive and at the same time properly maintain and enlarge their facilities as circumstances may require. To help bring about this condition, it is provided in the act that if from rates fixed so as to yield a fair return upon the value of all the roads in a specific group, certain individual companies in the same group should be able to earn more than 6 per cent upon the value of their property, then in that case one-half of the net operating income earned above 6 per cent from rates so fixed should be recoverable by the Government. This feature of the act has been much criticized, and by many has been held to be unconstitutional. Personally, I do not believe it is possible for private ownership of the railroads to endure in this country without such a provision as this in the act."

Discussing the labor provisions of the act, Mr. Willard said:

"It is manifestly important that there should be regularity and continuity of service by the railroads, and one of the important problems before Congress was to insure, if possible, such continuity by guarding against interruption of service which might be caused by misunderstandings and disputes arising between the railroad managers and their employees.

"It was urged by some that this provision of the act should be so written as to prohibit strikes upon the railroads. It was not possible to enact legislation of that character, nor do I think it would have been wise to enact such legislation at that time. I believe it would be a mistake for Congress to pass a law prohibiting strikes unless we are quite certain

Earnings, Expenses and Net Income, U. S. Railroads

that we shall be able to enforce such a law once it has been enacted. Personally I do not believe that we have reached a stage where we can feel confident that such a law would or could be effectively enforced. The matter was, therefore, dealt with, I think, in the wisest way possible under the circumstances. Congress created machinery and set up agencies by virtue of which the employees could feel assured of obtaining just as fair wages and working conditions without striking as they could reasonably expect to obtain even if they did strike.

"It may indeed be said that Congress by this act has made a preferred class of the railroad workers, because, so far as I know, this is the first and only time that Congress has ever definitely enacted that any particular class of the people should be given at all times and under all circumstances just and reasonable wages and working conditions. Of course, Congress did not do this primarily in the interest of the workers. Congress acted only as it had a right to act in the interests of the nation as a whole. Congress acted with a full realization of the importance of an uninterrupted transportation service in a country such as ours, but being unwilling to deprive the workers of their right to strike, it sought to provide machinery which would make it unnecessary under any circumstances for the men to stop work in order to obtain just and reasonable treatment."

A Labor Leader's Opinion

W N. DOAK, vice-president of the Brotherhood of Railroad Trainmen, suggested changes in the method of dealing with railway labor. The following steps should be taken, he said, in order to provide a proper solution of the problem:

1. The re-establishment of the Board of Mediation and Conciliation, with the right to bring about, if possible, voluntary arbitration.

2. The establishment of bi-partisan boards of adjustment, on which the railroads and the employees are equally represented.

3. The re-establishment of the rights of the respective parties to adjust any dispute by mediation, conciliation or voluntary arbitration, if possible, before reference to any board.

4. The maintenance, if necessary, of a board to act as referee, which for the time being, until otherwise changed, would be the U. S. Railroad Labor Board; this board to be appealed to only in case of deadlock by bi-partisan boards or in case of failure to adjust any dispute through mediation, conciliation or arbitration.

5. The establishment of a system or plan by which exact facts concerning wages, grievances and conditions of employment may be accurately obtained in a fair and impartial manner. The prohibition by law or otherwise of the circulation of propaganda concerning railroad disputes which has the tendency of alarming or inflaming the public mind.

Mr. Doak made this statement of the principles upon which wage adjustments should be based:

"In my judgment the proper and legitimate position is that transportation rates should be fair and reasonable and afford a fair return on capital legitimately invested; and, on the other hand, the wages of the employees should be just and adequate to afford a proper American standard of living, which should not only provide food and clothing, but allow for recreation, the education of the children, and give the employee the opportunity to lay aside funds for the care of such employee and his dependents in case of old age or disability. Wage standards and levels should be established independent of and separate from transportation rates. Neither should be dependent upon the other."

Railroad rates must come down if business is to revive satisfactorily, Secretary Wallace told the meeting. High rates, he said, will keep us in a state of agricultural and business confusion for a prolonged period. He summarized as follows the possible effects of failure to reduce railway charges:

First, to favor the farmers of South America and Australia at the expense of our own farmers, and all the

(Turn to page 972)

The Lumber Industry Moves On

"Westward the course of (the lumber) empire takes its way"

IS the center of the lumber industry of the United States moving again? Has the present source of lumber been so depleted that a new territory must be invaded? When most of the construction in this country was of wood, the pine forests of Maine, Vermont, New Hampshire and New York supplied most of the nation's demands for lumber. When this supply was exhausted, the white pine forests of the Lake states were invaded. In a short time, the Lake states began to drop behind in lumber production, and the yellow pine districts of the Gulf Coast began coming into prominence. Now the South is acknowledging that its timber resources are nearing an end and the states of the Pacific slope are supplying a large part of the country's annual consumption.

Previous to 1900 there are no accurate figures obtainable on the timber cut of the country. The records of production for the past twenty years, however, are sufficient to show the trend of the center of production and to furnish a basis for a prediction of what is to come.

Forty Years Ago

According to the *Timberman*, in 1879 the northeastern part of the United States furnished one-quarter of the nation's cut of lumber, the Lake states thirty-five percent, the Southern yellow pine forests in Virginia, Georgia, Tennessee and Kentucky produced enough to give that region a proportion of fourteen percent, while the Pacific Coast contributed only four percent.

Thirty years ago the Lake states held the lead. The New England states had dropped to twenty percent, the South contributed twenty percent, and Oregon and Washington had developed sufficiently to increase the output of the Pacific Coast states nearly nine percent of the total.

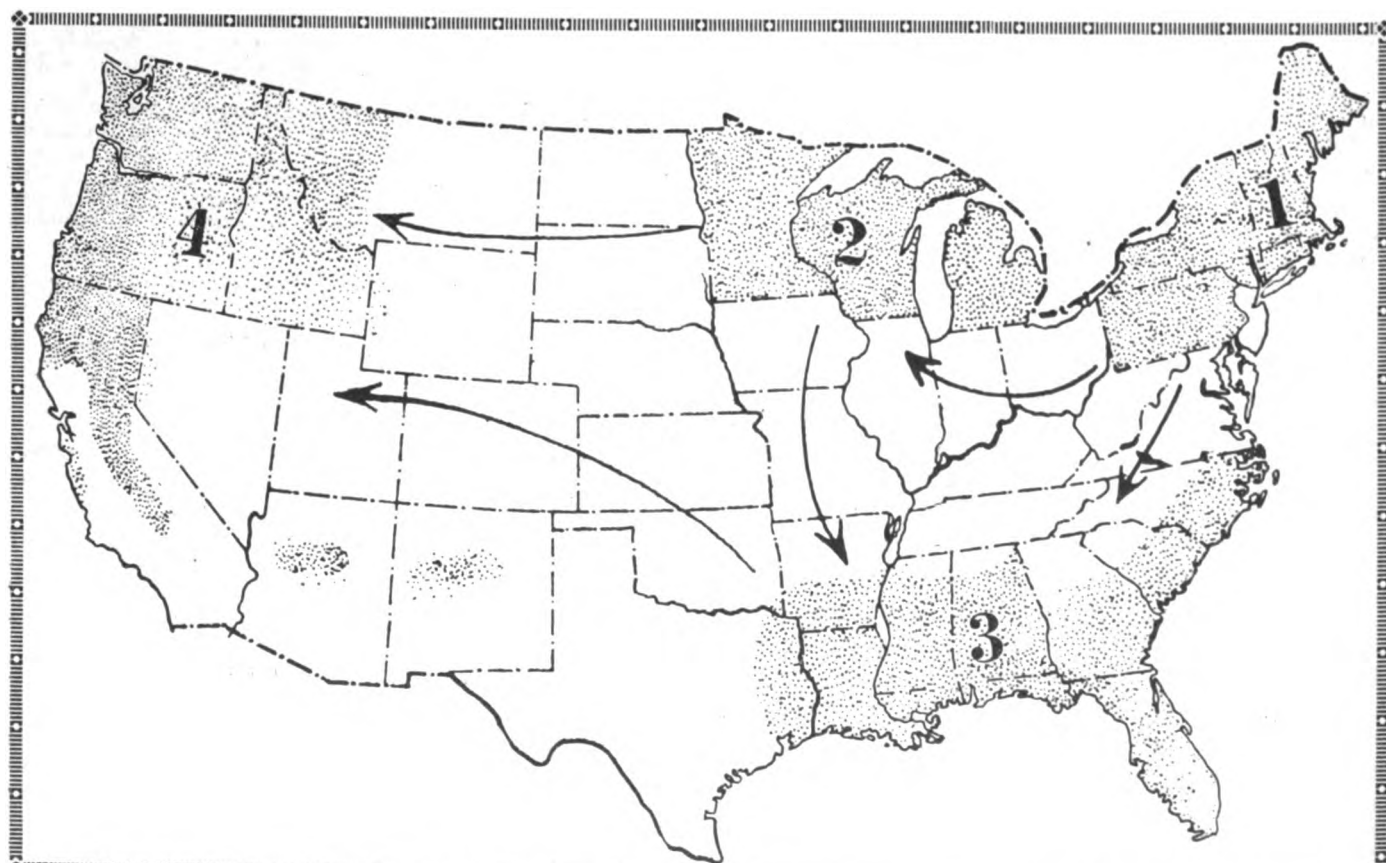

From this time on New England district and the Lake states continued to play a less important part, while the South came far to the front and the Pacific Coast states showed a gradual increase in production.

The 1919 figures show the Northeast cutting to have been less than eight percent of the country's production. The Lake states are still lower, with 7.5 percent. The South shows 46.6 percent for the year, while the Pacific Coast's proportion rose to 25.5 percent. Figures for 1918 complete the story. In 1918 the Northeastern states cut only 7.4 percent of the total of 32 billion feet. The Lake states cut ten percent. The South dropped to thirty-nine percent. The Pacific Coast states, counting only the region of western Montana, Idaho, Washington, Oregon, and California now have half of the nation's existing timber.

The Pulp Industry Also Moving

THE pulp and paper industry has also migrated westward in the last thirty years. The number of paper mills now located in Wisconsin furnish a striking evidence of this trend. The development of the paper industry and the value of paper enables its manufacturers to compete in the log markets with the sawmill operators, and paper manufacture always follows the lumber industry. The spruce and hemlock forests of the Pacific Northwest of the United States and British Columbia are now furnishing pulp, not only for paper mills of their own, but are also sending shipments East.

The *Timberman* believes that Portland will become the lumber center of the United States. It is admirably situated for this purpose, since it is midway between the north and south limits of the Douglas fir region, and at the gateway to the pine producing districts of the Inland Empire.

A Careful Study of Lumber Mills Indicates a Distinct Movement to the West and Northwest in Recent Years.

(The Timberman)

The Industrial Digest

WHAT'S GOING ON IN WASHINGTON

Voting the Ticket Straight

THE first test vote in the Senate on the McCumber tariff bill resulted in almost a straight party alignment.

Senator La Follette was the only Republican to vote with the Democrats, and Senators Broussard and Kendrick were the only Democrats who voted with the high tariff crowd. The vote was 37 to 21, and resulted in the approval of an amendment to the bill offered by the Committee on Finance placing a duty of 5 cents a pound on acetic anhydride. Majority leaders said that this vote indicates the majority by which the bill will pass the Senate.

The Democrats have announced that they will oppose the bill at every turn, thus increasing the likelihood that the debate will be prolonged. In the hope of speeding up matters, the Republican leaders have decided that the Senate will open its sessions at 11 A. M. hereafter, instead of noon. They are also beginning to hint at night sessions.

Bonus, Bonus, Who's Got the Bonus?

THE Senate is still looking for light on the bonus question. The Republican members of the Finance Committee, upon whom the chief responsibility for action rests, have announced that they will report a bill embodying substantially the same plan of bank and Government loans on adjusted service certificates that is proposed in the bill which passed the House. They have reached no final decision on how the money is to be raised, and they say that when they get their bill completely drafted they will ask President Harding for advice before they present it. Meanwhile business remains without knowledge of what to expect, and another element is added to the factors that are retarding industrial recovery.

John Bull Pays a Bill

CLOSELY connected with the bonus question are the negotiations over the British debt.

Senate leaders have been informed by the White House that negotiations are proceeding in a most gratifying way and that a settlement will be effected earlier than the public anticipates. A special representative of the British Treasury is shortly expected in Washington. Interest payments will probably have begun before January 1, 1923, and evidences of indebtedness, so far as the principal is concerned, will

have been deposited in the United States Treasury by that time. The Senators take the position that Secretary Mellon is too anxious to pay off the national debt in a hurry; declare that 3¼ billions have been paid since the armistice; assert that the bonus cost the first year will not be in excess of \$100,000,000, which can be made a general charge on the Treasury; insist that the Government, under legislative authority already given, can borrow all it needs, and at a rate as low as 3½ per cent; maintain that returning prosperity will wipe out prospective deficits. Some observers declare that the Senators are relying on the British debt settlement to pay the bonus, as arranged last November and reported by us at that time.

"Don't Give Up the Ships"

LARGE quantities of fireworks were set off last month by A. D. Lasker, Chairman of the Shipping Board, in connection with a "rate war" between American and British steamship lines engaged in the South American trade. The controversy was started when Lamport & Holt, a British concern, reduced the fare between New York and Rio de Janeiro from \$415 to \$315, between New York and Montevideo from \$475 to \$360, and between New York and Buenos Aires from \$490 to \$370.

The only competitor of Lamport & Holt in these services is the Munson Line, which operates Shipping Board vessels.

Both lines, according to Mr. Lasker, knew that a readjustment of rates was in order, but the Shipping Board expected that the Britishers would confer with them before making any reduction. When they heard about the action of Lamport & Holt, the Board held a special meeting, after which Mr. Lasker announced vociferously that the Munson Line would undercut the Britishers, charging \$295 to Rio de Janeiro, \$345 to Montevideo and \$360 to Buenos Aires.

The next day Lamport & Holt officials announced that they would meet the Shipping Board's reductions, at the same time declaring that they would not, under any circumstances, engage in a rate war. After this point both parties to the controversy decided that further public squabbling would be unseemly. They announced their intention to hold a conference, and further developments have not been made public.

Largest Oil Supply on Record

The 46,916,000-barrel production of crude petroleum during March was the highest ever recorded, according to the Geological Survey figures, and showed a 6,000,000-barrel advance over the same month a year ago. While this was accompanied by a sharp jump in consumption (3,500,000 barrels), heavy additions were again made to the stocks of oil on hand. Better than an 11,000,000-barrel increase in March brought the total to a new high record of 220,133,000 barrels. That supply is the equivalent of 140 days' consumption at the present rate.

The number of failures each month during recent years (reported by Dun's) is given below:

WITH THE FINANCIERS

Present Market Weakness Only Temporary

THE reaction in stock prices, after a long-continued rise, came according to schedule in the closing days of April. The market wisecracks had long been expecting it, and wasted little time in speculating over what caused it. It is pretty generally agreed that the reaction was due to the technical weakness of the market, acquired after a long upward pull. To put it simply, many speculators who had bought at low levels decided that it was time to sell in order to establish their profits.

It is interesting to observe that the market paid no attention to bad news from Genoa or elsewhere until it was good and ready. Several times during the period of rising stock prices the Federal Reserve governors met and failed to reduce the rediscount rate, but the boom continued merrily. The market disregarded the news completely until it grew top-heavy of itself, and then prices began to sag without regard for what was going on in the outside world.

Million-share days continued for some time after the reaction in prices set in. The volume of sales tapered off slowly.

Seasoned market observers appear to be of the opinion that it will be some time before the speculative issues start climbing again. The business cycle theorists, of course, believe that in the long run the outlook is bullish, and advise their followers to take advantage of the reaction to accumulate holdings for "the long pull."

Have Bond Prices Reached Top?

THE bond market continued firm, in spite of the speculative reaction. Investment experts are now beginning to differ sharply on the outlook. A great many of them think that the interest rate will drop still further and bond prices will continue to rise, but in opposition to this school there is arising a considerable number of observers who think that bonds cannot very well go much higher, for the present, at least. They point out that the gilt-edged rails and similar securities are now selling on a 5 per cent basis, which they think is a pretty low interest rate, in view of taxation conditions. They also are reminding investors that Liberty bonds

have just about reached par, and are asking the bulls how much higher they think the Libertys ought to go.

The opinion of a bond expert employed by a large trust company, given in private conversation, is pertinent in this connection. This man says:

"A lot of people talk about a continued rise in the bond market, but I can't see it. They say that interest rates will go back to the 3 and 3½ per cents of the old days, but I say, in reply, that a lot of conditions have changed. There was no heavy income taxation in the olden times, and I figured that the income tax ought to add about 20 per cent to the interest rate on taxable bonds. Moreover, in the old days there were almost no conservative industrial bonds on the market with any standing as gilt-edged investments. In the last few years large numbers of good industrials have been brought out. In addition, a lot of foreign bonds are now on the market, and more loans continually are being floated. A foreign country whose exchange is somewhat depreciated can afford to sell bonds in this country at a high interest rate, and if their exchange comes up before bonds mature, they will make money on the proposition.

Steel Merger Not Yet Completed

THE proposed merger of seven independent steel companies aroused increased interest when fourteen manufacturers, with their retinues of engineers and accountants, left New York in a special train for a tour of inspection of the plants that are to be combined. Stocks of the companies rose sharply amid rumors that the completion of the merger would be officially announced in the middle of May.

The independents involved are the Midvale Steel and Ordnance Co., Youngstown Sheet and Tube Co., Republic Iron and Steel Co., Brier Hill Steel Co., Lackawanna Steel Co., Steel and Tube Co. of America and Midland Steel Co. The name of the Bethlehem Steel Co., it is said, has been mentioned frequently in the conferences at which the merger is being planned. The Schwab Corporation, however, will not come into the combine at this time, although, according to the rumor, a way will be left for its entrance later. If the Bethle-

(From figures by Dun's)

The Industrial Digest

hem were added the new combine would rival the United States Steel Corporation in the value of properties and in production capacity.

The North American Steel Co. and the Federated Steel Co. are being considered as names for the new corporation, it is said. Kuhn, Loeb & Co. are conducting the financial operations of the merger.

Foreign Issues Brisk

FINANCING on behalf of foreign governments and corporations was unusually heavy during April. According to a compilation by the New York Federal Reserve Bank, the foreign bonds sold here during the month total more than \$200,000,000. The total since the beginning of the year exceeds \$500,000,000. The Reserve Bank adds:

"The offering of \$100,000,000 Dominion of Canada 30-year, 5 per cent bonds at par was the largest foreign issue sold here at one time since the \$100,000,000 French Government loan in May last year. Under the attraction of high yields, these issues sold rapidly and some reached substantial premiums soon after they were offered.

"The following table gives, approximately, the totals of foreign offerings in previous months of the year, together with a list of the more important April offerings through the 25th of the month. Their yields at sale prices are also given.

Month	Amount
January	\$92,346,000
February	57,768,000
March	155,513,000
April	
Dominican Republic, at 6%.....	\$6,700,000
Czechoslovak Republic, at 8.30%...	14,000,000
Rio de Janeiro, at 7.90%.....	13,000,000
Paulista Ry., Brazil, at 7.10%.....	4,000,000
Paris-Lyons-Mediterranean R. R., at 7.25%	10,000,000
Holland-America Line (guilders), at 6.30-6.90%	11,040,000
Dutch East Indies, at 6.24-6.48%...	20,000,000
Dominion of Canada, at 5%.....	100,000,000
Province of Ontario, at 5.05%.....	15,000,000
Other Canadian issues.....	12,790,100
Manila Electric Co., at 7.10%.....	22,500,000
	209,030,100

Total, Jan. 1 to April 25..... \$514,657,100

"Domestic corporation financing was active, and included

several large issues, among them \$60,000,000 New York Central Railroad long term 5 per cent bonds, offered at 5.30 yield. Bonds continue to predominate as a form of financing, though stock issues have become more frequent. During the last two months, the 8 per cent rate among corporation issues has practically disappeared, and there is a widening proportion of offerings at yields between 6 and 7 per cent."

Rail Revenues Increase

MOST of the Class 1 railroads which have filed their March reports with the Interstate Commerce Commission show a considerable increase in net operating revenue over March, 1921. One hundred and twenty-three of the 201 roads in Class I showed a net operating income of \$61,678,000, compared with \$18,563,800 for the same railroads in the same month of last year. In order that the entire class may realize a return of 6 per cent on the tentative valuation of the roads, the net operating income of all 201 would have to be \$85,895,700.

The Atchison, Topeka and Santa Fe reported a net of \$2,689,178, an increase of \$941,629 compared with March, 1921. Its gross earnings were \$16,624,115, against \$18,393,136 in the same month a year ago.

The New York, New Haven & Hartford reported gross of \$10,202,920 for March, compared with \$9,831,936 a year ago. Net operating income was \$1,775,085, compared with a deficit of \$337,163 in March, 1921. Rock Island's gross was \$10,270,841, a decrease of \$1,593,859. Surplus after charges stood at \$464,427, against \$925,384.

The Baltimore & Ohio showed an improvement in both gross and net for March. Gross was \$18,614,749, against \$16,217,398 for 1921, with net at \$3,081,212, compared with \$2,318,654 in 1921. The Lehigh Valley reported gross of \$6,732,239, compared with \$6,069,085 in March, 1921. Net operating income was \$1,220,462 for March, against a deficit of \$485,565 the previous year. The Wabash, Norfolk & Western, Cleveland, Cincinnati, Chicago & St. Louis, Chicago & Northwestern, Chesapeake & Ohio, and Norfolk Southern all showed improvement in net for March, compared with March, 1921.

The report of the New York Central Railroad Company shows a net railway operating income of \$4,555,930, an increase of \$1,482,984 compared with March, 1921. Gross income for March was \$27,598,745, or \$1,272,123 more than a year ago, while operating expenses were cut \$170,546 from last year to a total of \$21,634,489.

IN THE MANAGER'S OFFICE

Motion Study Principles

TIME and motion study have become recognized as essential in modern industrial management. Eric Farmer, a British authority, writing in *Engineering and Industrial Management*, develops the subject from the personnel rather than the production standpoint. His conclusions, although in partial agreement with the American viewpoint, will probably provoke a great deal of adverse criticism from those who have developed time and motion study to its present status. His contentions are: (1) All time and motion study must be undertaken in the interests of lessening fatigue and never in the interests of increasing production. When a proper system is carried out increased production will probably result, but if increased production is made the objective the true issue becomes confused and what pretends to be a scientific investigation degenerates into a process of speeding up. (2) The underlying principle of motion study is rhythm and not speed. The best movements are the easiest and not the quickest. (3) The proper use of time study is for the analysis of an operation in order to suggest lines of improvement or to determine the relation between processes rather than for standardization. All the effort of the investigator should be concentrated on lessening fatigue and increasing the ease with which the operation can be performed; other things being equal, the operators will set their own standards, which will satisfy all concerned. (4) Time and motion study are only parts of a whole region of study affecting the human element in industry and can only be carried out in conjunction with the study of other equally fundamental problems.

Overhead Costs

F BRUGGER, speaking before the New York section of the *Industrial Cost Association*, discusses four methods of distributing overhead costs. They are: (1) application on material, (2) percentage on direct labor, (3) productive man hour rate and (4) machine rate.

The first is limited in its application because of fluctuations in the price of materials. The percentage on direct labor method

gives approximate results if departments are properly apportioned and has the advantage of simplicity. The productive man hour rate is based on the number of hours spent on each job and is adapted particularly to plants where labor is paid day rates. Under the machine rate each of the individual expense items is analyzed and distributed to production centers. Production centers may be a machine, a group of related machines, a gang of men or any combination of allied functions. This method is the most accurate of the four. The following points determine whether or not it is practicable to use the machine rate method in a specific plant: (a) The relation of expense which can be traced directly to the different machines to the total expense and the total manufacturing cost; (b) the degree of similarity in construction processes for the various lines of products, and (c) the expense involved in operating the method.

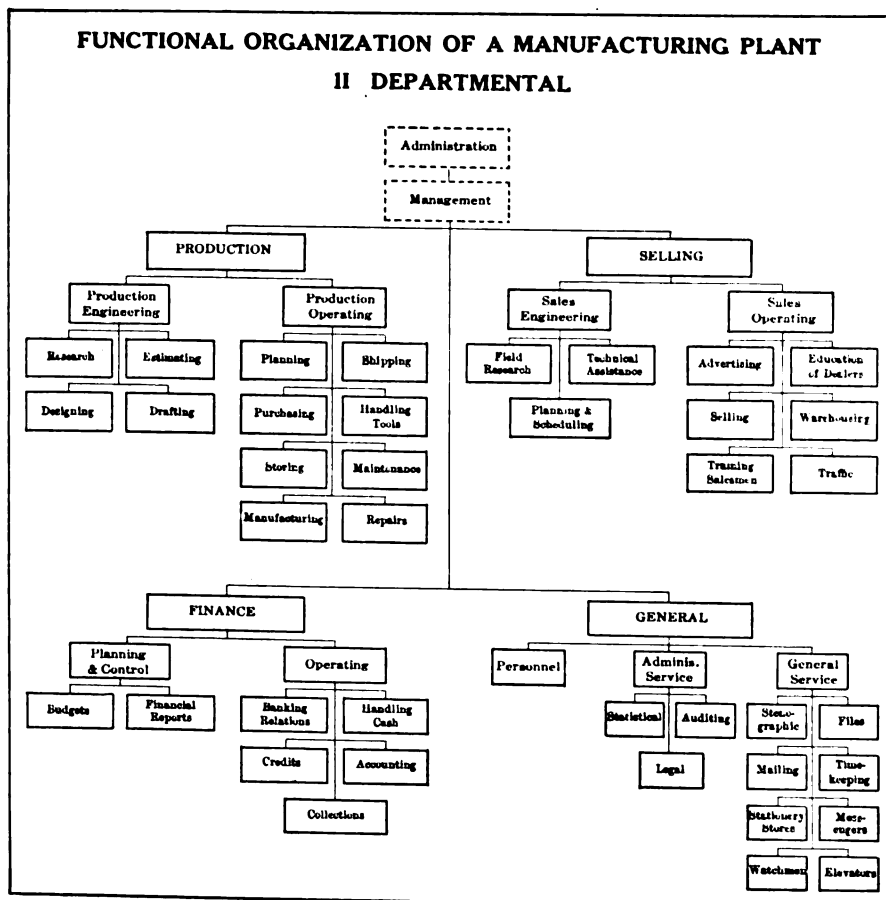

Inspection Room

IN laying out a production department one of the most important considerations is the relation of lines of construction to inspection and salvage. R. S. Snell, in *Factory*, advocates the location of the inspection room in the center of the assembly floor. Material thus arrives with a minimum of travel. Parts rejected are conveyed directly to a salvage substation and those passed leave in the opposite direction for the store rooms. In this manner construction, inspection and salvage are accomplished with the least material movement.

Man Hours

THE desirability of knowing the exact time an order passes through various departments on its way to the shop is evident. L. J. Barrows, in *Factory*, suggests time stamping and initialing the order in each department. In this way a record is obtained of the clerical minutes per order and each department is spurred on to complete its share as quickly as possible since the responsibility for delays is easily traced.

This suggestion, while practicable for speeding up the individual order, makes it difficult to obtain the average

Functions of a Typical Industrial Plant

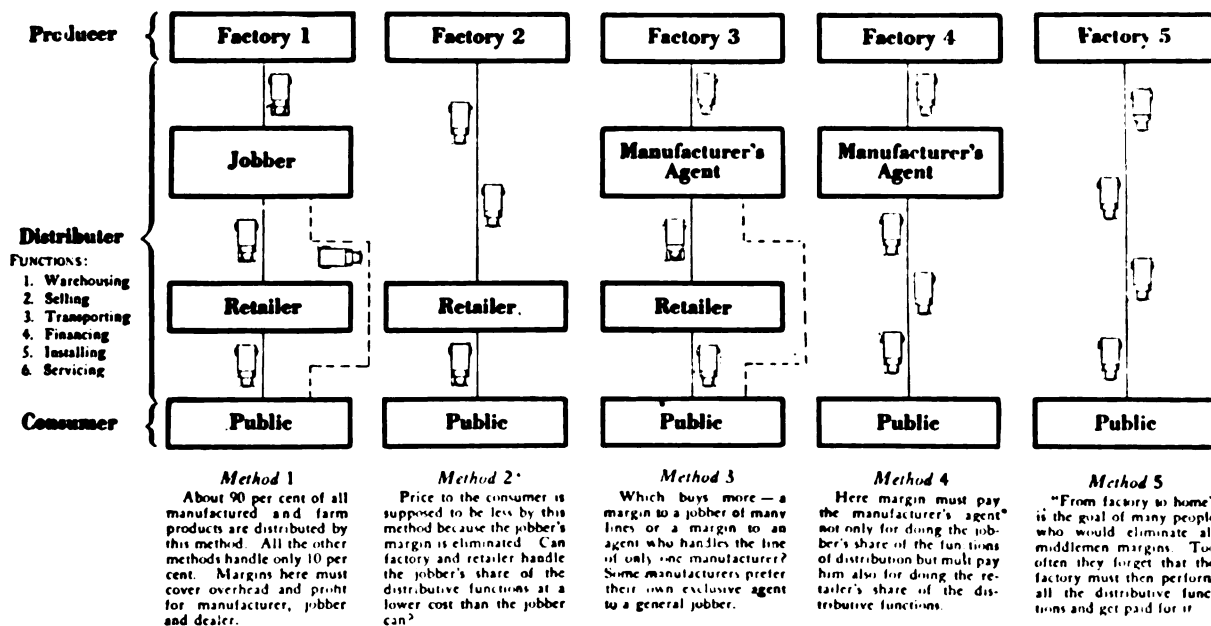

This chart is second in a series based to a large extent on lectures given at the Bureau of Personal Administration by Warren D. Bruner

Margin Enters Into Every Method of Distribution

Margin is payment for the cost of performance (overhead) plus a reward (profit) for doing it. The cost of distribution begins in the manufacturer's overhead. Distribution breaks into at least six broad functions: warehousing, selling, transporting, financing,

and often installing and servicing. No matter how many middlemen there may be between the factory and the home, several or all of these functions must be performed by somebody. Further, the performance must be paid for. Middlemen may be eliminated, but the

functions and their cost cannot be eliminated. It becomes, then, not so much a question of eliminating middlemen who are specialists on certain functions but of holding down the cost of performance and reward to a fair minimum.

(McGraw-Hill Industrial Letter)

clerical minutes per order for the entire plant without a great deal of unnecessary work. The following method will determine the efficiency of the office as a whole: the man hours per year spent in handling orders divided by the yearly volume of orders and multiplied by sixty will give the average clerical minutes per order. In figuring man hours the time of every clerk or department head who does work related to an order should be included. This embraces correspondence relative to orders and filing. The time per order varies from a few minutes in efficient mail-order houses to several days in large factories where pricing and estimating become involved.

Keeping Tabs on Work

WILLIAM DAVIDSON, writing in *Factory*, describes a system which notifies all department heads in advance of work that is coming to their departments. On a ten by twelve-inch card all the information necessary to follow the progress of the work is given. Along the top the days of the month are shown and due dates in the various departments indicated by different colored metal tabs. Advance notice cards are made out from this information and sent to each department that will handle the job. As soon as the job is completed a production move slip, pasted to the back of the card, is filled out and returned to the planning department.

The Early Quitter Problem

GETTING employees to put in a full day's work has always been a serious problem for all employers. *Factory* describes some ingenious expedients for insuring full-time production. In one plant the whistle was sounded five minutes before starting and quitting time. Five minutes before starting time the men were expected to register on the clock so that they could be at their machines when the final whistle blew. They were allowed to quit at the evening preliminary whistle so that they could register out on time. To overcome the habit of employees washing and changing

clothes on company time another factory placed the time clocks between the washrooms and the entrance to the shop, cards not being stamped until employees were ready to go to work in the morning or had finished work in the evening. Much the simplest device was that of an Ohio concern which locks its locker rooms during the working hours and does not reopen them until the whistle has blown in the evening!

Reducing Unfinished Orders

THE problem of unfinished orders is a factor which can be minimized if not wholly avoided, says *Engineering and Industrial Management*. Unfinished orders may accumulate through faulty planning, the breakdown of machines, waiting for material or from preference given to rush orders. To discourage accumulation of unfinished orders all such orders should be returned to the planning department, where they are listed with the reasons for delay. The planning department can then readjust its schedule to absorb this delayed work.

Loss from Delay Hours

IN all large plants the loss in output due to delays may become of considerable importance, says J. J. Martindale in *Factory*. An analysis of existing delays with the determination of reasonable standards can show large, continual savings. If a plant is operating on a declining market there is no demand for greater production and the savings in eliminating delays can be applied to a reduction in the payroll. If the plant is operating on a demand market and increased production is wanted, the possible gain is still greater.

In order to obtain the amount of delay hours, job tickets of a different color from productive job tickets are made out for delays of one-tenth of an hour or more. A standard nomenclature should be developed and the cause of the delay shown on the ticket. Delay hours as taken from the work tickets are entered on a daily record. A standard delay percentage for each classification is determined and an incentive offered to foremen to decrease delay periods.

LABOR

Employment Increasing

ENCOURAGING reports are coming from all sections of the country in regard to the improvement in the employment situation in the United States. Although there was a temporary slump in January and February, the climb upward began again in April, and it is believed that by the first of May, the midwinter slump will have been more than counterbalanced, with a strongly continuing tendency toward greater improvement. In Philadelphia, which may be used as an index for the country, the building trades are busy and a shortage of mechanics is beginning to appear. Textiles are said to be reasonably normal, the metal trades have reported an improvement, lumber and its manufacture is fair, and even the railroads and shipbuilding plants are beginning to call for men. The leather, chemical, paper, candy, and some other industries are still more or less retarded by the effect of foreign competition, but confidence is gradually being restored.

In attempting to clear up "misconceptions" which he said arose from his previous testimony before the Lockwood committee, investigating union labor conditions in the building trades, Samuel Gompers, president of the American Federation of Labor, recently declared that he favored legislation to get labor its "rights," but opposed legislation or administrative process to remedy the abuses of power by labor unions. He admitted that the elimination of abuses such as those exposed by the Lockwood committee would strengthen organized labor, but he believes that such abuses should be remedied only by voluntary actions of the unions. He attempted to show that the courts had trespassed on the rights of labor by the decision holding as unconstitutional child labor legislation, factory and tenement house legislation and other acts passed at the suggestion of organized labor.

Wage Reductions to Be Fought

THE determination of union labor to resist any further wage reductions is indicated by the threat to call out 100,000 organized paper workers and other unorganized groups in that industry, if the employers enforce their proposed additional ten per cent. cut in wages. The strike call is being held in abeyance awaiting the result of a workers' referendum vote.

According to the *American Contractor*, in upper New York State the efforts of employers to further reduce building costs have resulted in threats of strike action from the men involved. In Syracuse the declaration for the open shop for lathers at ninety cents an hour by the Syracuse Builders Exchange on April first leaves only three trades in that city whose wages have not been revised by employers. The bricklayers, carpenters, plasterers and painters of Niagara Falls went out on strike early this month rather than submit to a proposed cut of from ten to fifteen cents an hour. It is claimed that there are more than 1000 building workers idle in that city.

Railroad Strike Expected

IN the opinion of railroad labor spokesmen in Washington, the country may soon be faced by a nation-wide railroad strike. The railroad unions believe that there is no further hope of enforcement of any but anti-labor rulings of the Railway Labor Board since the recent decision in the Federal Court that the board had no authority to censure the Pennsylvania Railroad Company for its refusal to obey an order of the board to meet its shop employees in conference as to

working rules. However, in the event of a strike, an effort will be made to keep it absolutely distinct from the coal strike. It is said that the chiefs of the American Federation of Labor do not want to advance either the idea of general strike tactics, nor the movement for nationalization of basic industries.

Clothing Workers Sign New Agreement

A NEW agreement between the clothing workers and the manufacturers in Rochester, N. Y., was adopted May 1. It covers the next three years, but contains a provision for a wage adjustment by either side each year. The signing of this agreement, following the renewal of a similar arrangement between the Chicago manufacturers of men's clothing and their forty thousand employees, insures industrial peace for these two important clothing centers for the period mentioned. The essentials of the Rochester agreement are: a forty-four hour week, overtime at the rate of time and one-half; equal division of work during slack periods among all workers in the shop; preference in hiring, in time of unemployment, to be given workers who have been employed in Rochester shops doing work for members of the Clothiers Exchange; prohibition of stoppages and lockouts. It is also agreed that the form of industrial government in the clothing industry already established in all of the important clothing centers in the United States shall be continued, and that an impartial arbiter shall promptly adjust all grievances and complaints for the review of cases of discipline and discharge and for the interpretation of provisions of the agreement. The employers have also promised to recognize the obligation of workers who are members of the union to pay their union dues.

Deadlock in Textile Strike Continues

THERE appears to be no prospect of the settlement of the New England textile dispute in the immediate future. It is estimated that the production lost through the strike is now 108,000,000 yards, and that this amount is increasing at the rate of 2,000,000 yards daily. Mill operations in the States of Rhode Island and New Hampshire have been almost entirely suspended for the last ten weeks.

Average Earnings of Miners

ACCORDING to a recently published summary of conditions in the bituminous field, the average earnings of the miners in 200 mines, covered by the survey, came to \$1,357.40 a year a wage below the minimum requirement for a family of five, as fixed by a number of organizations. A study of 246 miners' families shows that 146 had a deficit at the end of the year. The average deficit of all the families was \$115.80. An interesting table shows the earnings of a husband-miner, and the total income of the families. In the latter column are included what the husband may earn at odd jobs, the earnings of the wife, earnings of the children, income from boarders, lodgers, etc. The total income which the miner is able to obtain from all sources for the year is reported to average \$1,178.09.

No Improvement in Unemployment in Europe

UNEMPLOYMENT in Europe shows very little change for the better. In England there was only a slight improvement in February over January; the percentage of unemployed among members of trade unions was 16.3 against 16.8. Changes in wage rates taking effect in February showed

How Cartoonists Regard the Coal Strike

Varying Interpretations of the Coal Strike Situation Regard It as Shoving Away the Business Revival and as Leaving the Innocent Public Groping in the Dark

a net reduction of 390,000 pounds in weekly full-time wages of over 2,400,000 workers.

Unemployment in France, as reflected by employment exchanges, has decreased considerably, and is now stationary.

German figures, based on out-of-work donations, show an increase from 164,958 on January 1 to 196,103 on February 1. Returns from trade unions show that out of a total of 5,797,753 members, 190,614, or 3.3 percent, were employed at the end of January.

Holland reports that on February 11, there were 86,842 unemployed men and women, an increase of 10,000 in five weeks.

Denmark estimates there are 99,000 unemployed out of 280,000 workers reported on March 13.

Belgium's latest reports show out of a total of 756,575 workers, 49,851 totally unemployed, and 36,232 partly employed.

On January 1, Italy had 541,779 persons totally unemployed, compared with 512,260 on December 1. Those partly employed on January 1 numbered 178,662 against 181,002 on December 1.

At the end of February, Norway reported unemployed numbering 47,200 compared with 41,500 on January 10.

Sweden had 140,883 persons unemployed on December 31 last, a percentage of 33.2 percent of union membership. This percentage decreased to 20.2 percent on January 31.

Unemployment figures in Switzerland show a steady trend upward. And from Vienna comes the report that the number of unemployed on January 14 was 27,000 as against 18,000 at the beginning of 1922.

Strike in British Engineering Industry

AN official inquiry into the lockout of 600,000 workers in the engineering industry in England is now being made. The dispute is largely over the rights of management in work-

shops. Although the shops were recently opened for the employment of men wishing to resume work on the employers' terms, it is reported that very few availed themselves of this opportunity. The unions appealed to the employers to lift the lockout pending the outcome of the inquiry but Sir Allen Smith, the chairman of the management committee of the Engineering Employers' Federation, refused to do this, saying that the court had no jurisdiction in the matter. This is one of the biggest labor problems England has had to face for some time, and industrial leaders are anxiously watching.

German Railroaders Won Recent Strike

ALTHOUGH the German Government has insisted that the settlement of the recent railroad strike has been brought about without any concession to the strikers, and that the participants would be subjected to disciplinary measures, a bill was recently introduced in the Reichstag raising the salaries of all its employees of the twelve first classes, which includes all the railroad force, except the very highest officials, as well as all the postal employees, etc. from 6,400 to 9,800 marks yearly, an increase of from thirty to fifty percent. It is said that during the railroad strike postal employees and various other minor officials of the government had not only expressed sympathy with the strikers, but had considered a strike to aid them. In regard to this increase the *Wall Street Journal* says: "While there is no legal proof that the action of the government is to carry out any bargain made with the railroaders at the time the strike was settled, nor that another bargain was also made with the postal employees to restrain them from participating in the strike, there is in the minds of the not entirely unsophisticated what the late Artemus Ward characterized as 'a powerful suspicion'."

ADVERTISING

The Effect of Once-In-Never-Out Advertising

AN interesting story of what continuous advertising accomplished in the case of Kitchen Klenzer is told by G. A. Nichols in the April 27 issue of *Printers' Ink*. When Fitzpatrick Brothers started marketing Kitchen Klenzer in Chicago twelve years ago, a newspaper advertising schedule was adopted, providing that copy should be run forty weeks in the year. It was believed that each newspaper had its own individual reader interest, that if it was good enough to use at first it was too good to quit, and that a succession of advertisements in a newspaper has much the effect of a serial story.

Looking back over the strenuous efforts made to capture the Chicago market—their first objective—the company officials are certain that their victory was due primarily to the fact that they started with a settled policy of manufacturing and merchandising that has not been deviated from, and they developed one market thoroughly before moving on to another.

The Fitzpatrick selling organization never leaves a market after entering it. The intensive development of the Chicago trade was kept up constantly and even now, when the distribution has become national, there is no lessening of the amount of advertising.

The company's promoter makes frequent addresses to jobber's sales forces and always is ready to give personal counsel in any phase of salesmanship. Frequently, at the request of a jobber's sales manager, he writes personal letters to each member of the sales department. These letters reiterate various phases of the story of Kitchen Klenzer, placing particular emphasis upon the continuity of the advertising.

An endeavor is also made to aid the retail grocer in every possible way. This service is particularly important just now, inasmuch as so much of the grocery business in the large cities is going to the chain stores. The Kitchen Klenzer people consider they are doing the grocer a real service in showing him the turnover advantages of advertised goods, and how they can be used in his present time of need to reduce selling resistance and make his invested capital work to the utmost limit.

Educating Associations to Cooperate in Advertising

ONE reason why every seller of merchandise should be interested in the advertising campaign now running on Spanish Green Olives, says Roland Cole, writing in the April 27 issue of *Printers' Ink*, is that it is the culmination of several years' effort. Another reason is that the association of American importers, whose money is paying for the campaign, is not a large group numerically, and not all members are contributing to the advertising fund. Those who are paying could print their names in the advertisements if they wished and share more directly in the credit and benefits. But all advertisements are signed "American Importers of

Spanish Green Olives." Mr. Cole regards this fact as creditable enough to be regarded wholly apart from a description of the campaign. He points out that there are literally hundreds of associations that should be advertising cooperatively. Most of these associations are larger (in number of firm memberships) than the Spanish olive importers. But the reason cooperative advertising is not more popular is because in many associations there are firms who fear their competitors will get as much good out of it as they will. For this reason the campaign of the Spanish Olive Association is particularly important, because it illustrates how the anti-advertising group in any association may be educated.

It is interesting to know how the expense of the campaign is to be paid. The arrangement is an excellent one, since it provides a fund large enough for an adequate campaign and one extensive enough to attract the attention of jobbers and retailers and give them an excellent start for local advertising in their own sections in case they wish to do it. Members of the association may also advertise on their own account and thus capitalize on the association advertising.

The growers, or curers, all of whom are located in Spain, pay a per gallon tax on the number of olives shipped. The American importers pay a tax on shipments received. The amount of tax is large enough to provide for the present campaign and also to continue the campaign on its

present scope. Should the campaign prove effective and larger shipments of olives be received, a larger sum of money for a more extensive campaign will be automatically provided.

Increasing Sales with Demonstration

WHAT'S the use of making a demonstration? The trade knows the goods." Too often, says B. J. Munchweiler, in *Hardware Age*, this attitude is taken when the sales talk could be made much more effective by prefacing it with an intelligent demonstration. But in employing the demonstration idea to sell goods, the points to be emphasized must be carefully selected. The prospect must be considered always—not the manufacturers, sales manager, or yourself, but the man who is going to buy. You must be prepared with statements which will tell him what your goods are and what service they will render.

Can Factory Advertising Sell Goods?

IN the opinion of Harry Varley of the George Batten Company, writing in *Advertising and Selling*, every advertiser likes to see a lifelike picture of his factory splashed over his ads. Although there is not as much value in the picture of the factory as the advertiser often thinks, it attracts considerably more attention than the average advertising man likes to admit. One important use to which this idea may be put is in illustrating some basic feature of the product by showing a series of factory pictures.

Value of Railway Plant Compared with That of Agriculture and Manufacturing Industry

(By Chicago Railway Equipment Co.)

EXPORT • IMPORT

Exports Show Increase

IN line with the scattered reports of increasing exports are the figures published by the Bureau of Foreign and Domestic Commerce for March. Exports for March total \$332,000,000, which is the highest export figure since October, 1921, and nearly double the exports for March 1914, although less by \$55,000,000 than the exports for the same month last year. Imports amounted to \$258,000,000 against \$252,000,000 in 1921 and \$183,000,000 in March 1914. Inquiries received by the department show an increase in the proposals for the purchase of goods over applications for agencies, an indication of considerable business recovery in a number of countries.

Trade with Orient Increases

FAR Eastern trade is reviving, with improved business conditions in China, particularly in the ports. The usual spring buying in the upper Yangtze and North China regions is interrupted to some extent by the political situation. In Japan, deflation, gradual, but actual, is bringing lower prices and living costs. This development will, if continued, bring Japan into line with the general world price level and make for fundamentally better conditions. In Australia, general business conditions are reported fairly satisfactory, and the outlook is more encouraging.

British Coal Production

BRITISH trade returns bear out our own reports of increasing business, March exports being the heaviest for twelve months. The market for raw materials was especially strong. Coal production for two months averaged nearly 5,000,000 tons per week, leaving available for export in March the largest tonnage in recent years. Iron and steel exports were the highest since July 1920, while textile exports are slowly coming out of the February slump.

Currency Stabilization Essential

IN Western Europe, trade continues dull, and, in fact, waits on improvement in the exchanges and the removal of government restrictions on trade and exchange. It is on this account that the Genoa conference is regarded with such attention. The limitation and reduction of the issue of paper currency, and stabilization of exchanges would prove a sound starting point for tremendous revival of trade.

A New Service

TO meet the demand for protection on the part of the foreign buyer, which has been recently evidenced by a tendency to introduce extraordinary conditions in letters of credit, and requests from foreign banks that American bankers provide an adequate means of checking up shippers' performance of contract before releasing funds for payment on commercial credits, a new company has been organized in New York. Its service consists of a disinterested survey of export goods at the time of delivery to steamer, in order to ascertain all pertinent facts and certify to them in certificate form. They will report on the following conditions:

1. Time of delivery of merchandise to steamer. The position of the steamer at date of delivery. Advertised date of sailing. Ports of call in order.

2. Actual conditions of packing or cooping. (They will supervise such re-cooping or re-conditioning as may be necessary to insure safe transportation of the cargo.)

Port marks—Will see that port marks are proper and distinct to insure correct delivery at destination.

Stowage position in vessel as a precaution against damage by improper temperature, ventilation or by contact with contaminating cargo.

3. Quality—as a record of quality the inspectors will draw representative samples from the shipment (certain commodities excepted.) Such samples will be sealed, labeled, filed.

Every Day Is Moving Day

Industry's back-breaking jobs are

The pictures on these pages show material handling apparatus of the stationary type—known as conveyors.

(Above) A combination conveyor system consisting of several units of the roller chain type. It is used for loading heavy sacks on ships in Norfolk harbor and saves the labor of twenty-five to thirty men.

(Oval) A great magnet crane with a lifting capacity of 40,000 pounds. It is operated by electricity and is used to unload large steel billets from freight cars and dump them in the yard.

Above is an endless bucket-belt conveyor at work in a coal yard, scooping coal into bins where it is stored preparatory to dumping into wagons.

A different type coal handling device, shown below, is a hopper with a belt conveyor on rollers. The flexible belt receives its load through the hopper and carries it to the crusher or pulverizer.

(Below) Combination chain and roller conveyor used to carry boards and stack them prior to "dressing," as shown at extreme right of picture.

(Above) Electric cab-controlled overhead crane transporting miscellaneous machinery from trucks in the yards of an engineering company in Detroit.

With Conveyors On the Job

easily accomplished with their aid

The spiral gravity conveyor above is the means for loading cans of petroleum on ships. The chute is lowered into the hold of ships and receives its load by means of the inclined arm (seen through the base of the derrick).

(Above) Electrically operated overhead lift and conveyor. The device runs on an overhead rail and transports heavy automobile parts. Efficient and convenient is the portable leather belt conveyor shown below.

(Below) Types of overhead conveyors. Both are electrically operated and run on rails; the system at the left operating on tracks. For heavy work where speed is not the first requisite the overhead power system has been found most efficient.

Speed is the advantage of the endless chain conveyor, shown in the oval, which carries logs to the saw room in a Southern pine mill.

AUTOMOTIVE

Seven Hundred Flights—No Accidents

THE increasing safety of air transportation is evidenced by the latest report of the Aeromarine Airways, the oldest air transport enterprise in America. Not a single passenger or employee was injured during the seven hundred and thirty-five separate flights made by the flying ships of this company during the last six months. This record, says *Aviation*, is the best demonstration of the safety which can be achieved by airworthy machines and a capable personnel.

It is pointed out that new means of transportation have always had to fight an uphill battle against public prejudice

resulting from ignorance and fear. Although the airplane has not yet emerged from this period, public opinion is favorably inclined toward the flying machine. And demonstrations of the kind furnished by this "Black Tail Fleet" are certain to increase public confidence. A record of safe flying, produced repeatedly, cannot fail to impress people with the fact that the air transport is being woven into the fabric of civilization. At the same time, it is a reminder to those engaged in aviation that safety can be achieved only through the most careful operation.

Loth Guide Cable for Flying in Fog. Description of the French experiments with this new device. It is intended to guide aircraft safely into their hangars, or at least, home-flying fields, when the fog is so heavy as to prevent the pilots seeing anything on the ground. It is an adaptation of the method perfected during the war for guiding ships into or out of port during foggy weather. In principle, it rests on the fact that a magnetic field of considerable intensity is created around a cable through which high-frequency alternating current is passed, but with the ends of the cable earthed. By suitable instruments, this field can be detected. After rigging up the cables it is a simple matter to equip the airplanes with these instruments, so that when coming home in a fog, the aviator may pick up the field of the grounded cable, and thus find and follow the cable itself. The article describes the practical difficulties met and overcome in proving this out. *Aviation*, 4-10-22, 1350 w. MAH.

Future Development of Fighting Airplane. This military man feels that there will be but two types of fighters developed, one for high-altitude fighting, and consequently a fast climber, and a lighter machine for "dog" fighting. The former will be a large, heavy machine well armed, and with considerable steadiness, as one would suppose from the greater size and weight. The latter

will be lighter, carry few passengers, probably but one, be armed very lightly, and will be of exceedingly high speed and superlative maneuvering ability. The Major continues to define the two, and to outline their ultimate forms, taking up such important factors as armament, view, ability to withstand damage, fire, performance, armor, size, power, etc. MAJOR F. M. GREEN, *Aviation*, 3-20-22, 4100 w. MAH.

Modern Upholstering for Fine Motor Cars. Part of a series on body work and upholstery. This takes up especially the matter of comfort and the influence good upholstery has upon it. The question is viewed from both the British and the American viewpoints. Pleated button work compared with plain flutes. Upholstering tendencies in the two countries. *Automotive Manufacturer*, 3-22, 2300 w. MAH.

Practical Uses of Aerial Photography. Further development presented previously in all the automotive publications concerning aerial photography, and especially the recent exploit of one firm in mapping Manhattan Island in 69 minutes, elapsed time. The use of these aerial maps as the groundwork for line maps is shown and explained also. Other uses and advantages of the aerial map are indicated. *Aviation*, 4-10-22, 3500 w. MAH.

Improvements in Aircraft Power Plants. Author points out tremendous progress made in last few years, and outlines some of his ideas as to the further improvements which may be expected in next few years. He takes up a few of the big outstanding points in design, notably drawbacks of present large sizes, need for further reduction in weight and overall dimensions, rotary vs. stationary engines, radiator design, fuel systems, lubrication systems, induction systems, costs, etc. R. J. DOLPH, *Aviation*, 3-20-22, 3060 w. MAH.

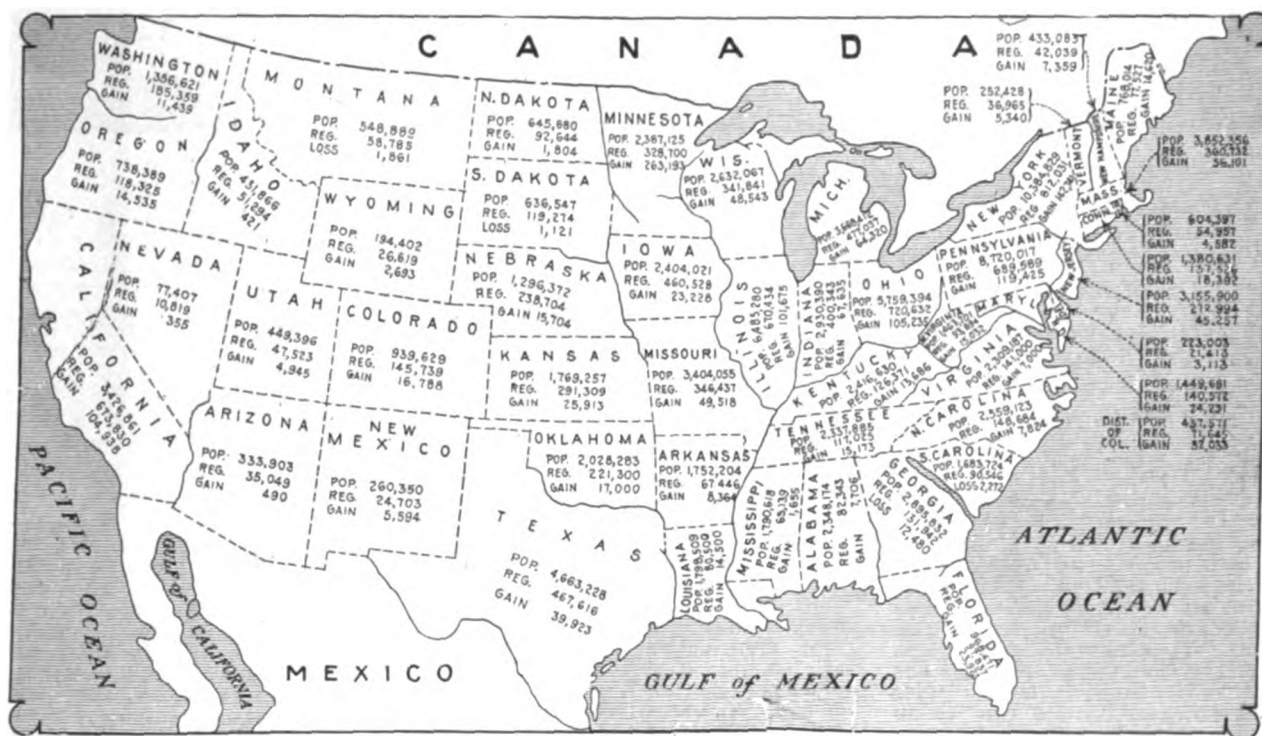

Standardization and Aerodynamics. Discussion of a paper on this same subject, referred to in these columns. The Italian designer feels that the stage of uncertainty has passed, now that the motor has reached a stage of development where no revolutionary changes in design need be expected, but rather improvement on the auxiliary organs. Planes can be improved only by a thorough study of the aerodynamical phenomena taking place in flying so as to be able to introduce the slight changes which will allow an increase in efficiency. LT.-COL. ING. R. VERDUZIO, *Aerial Age Weekly*, 4-3-22, 1800 w. MAH.

Human Machine in Aviation. The author says flying requires the development of a new special sense, the sense of flight. He develops this idea by pointing out the reaction of the average person to the various sensations of rising or falling, of gliding through space, etc. He also discusses the importance of the various senses and perceptions in flying, the physiological effect of altitude, of loss of oxygen on different types of persons, etc. EDWARD C. SCHNEIDER, *Aerial Age Weekly*, 4-3-22, 6200 w. MAH.

Aerial Photography. The tremendous field which this new subject has opened up for the use of planes, of cameras, of war-trained fliers and young men still to be trained, the great savings effected, in fact at times the accomplishment of what would otherwise be impossible; tremendous advantages of actual aerial view over artist sketches, views from the ground, maps or any other method, all these points and others are brought out in this continued article, of which the present is the conclusion. W. L. HAMILTON, *Aerial Age Weekly*, 3-20-22, 2050 w. MAH.

Motor Cars Exported from United States in 1921 by Regions of Destination
(From U. S. Commerce Reports)

One Motor Vehicle for Every Ten Persons in the United States

The accompanying map will in some degree show the important position held by the motor car at the present day. According to the car and truck registration for the year 1921 there were 10,505,660 motor vehicles in the United States. This shows a gain of 1,573,202 over 1920, and amounts to practically a self-propelled vehicle for every ten persons in this country. Motorcycle registrations dropped 27,024 during this period. (From *Hardware Age*)

Commercial Aviation Developments in Europe. Another part of this interesting outline of the work being done all over the world. This instalment covers Italy and Germany only, just as the previous one took up northwestern and western Europe. The author brings out one important point, that Germany has not been handicapped from the start by war machines, since, under the treaty terms, she was obliged to give up all these. Consequently, her commercial planes were designed and built primarily for commercial work. This situation explains the greater progress and superior stability of the commercial airplane companies there. W. KNIGHT, *Aerial Age Weekly*, 4-10-22, 3700 w. MAH.

Development of Cylinders for Air-Cooled Engines. Air cooling is coming back, whether developed by the war or through cry for economy. This author has applied war-gained, air-cooling experience to the design of cylinders. Details are given of cylinder in sizes, heat storage capacity of various shapes and sizes, cylinder head design, advantages of high compression, use of cast iron, valve and seat design and cooling, special materials, and other allied and pertinent topics. Much is made of the British B. S. A. light car, which has a two-cylinder, V-type, air-cooled engine, and of the R. A. E., 4D, air-cooled cylinders. S. D. HERON, *Automotive Industries*, 3-23-22, 5400 w. MAH.

Substitution of Motor Buses. Author cites case of New York and the Fifth Ave. Coach Co. for example of grow-

ing congestion on city streets, and the manner in which use of motor buses will relieve it. He claims the bus is more flexible, thus better suited to narrow, congested streets; buses can pass one another, or one or both can be held at a point for a time and make up the waiting time, can load and unload at the curb, thus leaving more of street free for other traffic, and keeping the passengers in safety; street cars slow down traffic, buses seem to speed it up, etc. He gives many striking facts to prove that the bus is with us to stay, and that properly managed, buses can make money in any large city. F. VAN Z. LANE, *Automobile Jour.*, 3-22, 2700 w. MAH.

Tractor Saves 66 Days' Man-Labor a Year. A study of reports of 684 tractor owners in the Southern States, just completed by the Division of Agricultural Engineering indicates great satisfaction on the part of these owners. Data shows also that the average saving by tractor was equal to the labor of a man for 66 days each year. For the two-plow tractors the figure was 63 days, for the three-plow machines, 78 days. Average acreage covered per day varied from 4.7 with two-plow disc and 5.3 with two-plow moldboard up to 6.5 with three-plow disc and 7.3 with three-plow moldboard. Article gives much additional data of value. *Agrimotor*, 3-15-22, 1400 w. MAH.

Airplanes in Mine Rescue Operations. Airplanes have possibilities in conjunction with rescue work of Bureau of Mines, for quickly transporting engi-

neers and oxygen rescue apparatus to mine disasters. Difficulties at present are: Distance of Air Service stations from Safety stations; suitable landing fields; difficulty of flying at night. Best used in those States where surface is comparatively level. E. J. BAILEY, *Arizona Min. J.*, 4-1-22, 600 w. CJW.

All-Purpose Tractor on Modern Farm. Author points out that early development of tractor was along two lines only, one breaking of prairie sod, and belt driving of separators for threshing machines. Later tractors have clung too closely to these two, the heavy, high duty machine for very rough work, and the lighter machine, primarily for belt work. He argues for a machine which is a cross between the two, one that will do everything the farmer asks it to do, an all-purpose machine. Claims farm tractor industry cannot go much beyond present position, if at all, until such machines are developed and pushed. J. S. CLAPPER, *Automotive Industries*, 3-16-22, 2800 w. MAH.

BUILDING-CONSTRUCTION

Industrial Building Affects Other Commodities

THE most encouraging feature of the boom in building is the large proportion of contracts for industrial and business buildings that have been reported for March. Business building awards for March of this year amount to \$49,257,800, as compared with \$22,715,800 for March, 1921, while awards for industrial building amount to \$24,270,200, as compared with \$10,640,200 in March, 1921. This type of construction is certain to react favorably upon allied industries. A greatly increased demand is already evident in the steel, lumber, cement and brick industries.

According to *Iron Age*, the volume of fabricated steel business closed in March—139,300 tons—was almost as much as

that of January and February combined, and was more than thirty percent better than the March average for the preceding ten years. For the first quarter of the year contracting has engaged about fifty-four percent of bridge and structural shop capacity, or only two or three percent below the average for the last decade. During the last week new structural work, requiring 17,000 tons, has appeared.

While it is probable that one result of the improvement in the building and construction field may be the increase in the cost of both labor and materials, it is believed this increase will be counterbalanced by the elimination of wasteful methods in building.

Some Facts on Warm Air Heating. Discusses importance of architect properly designing and seeing that plans are carried out for hot air heating systems to eliminate present source of complaints. Troubles not due to system itself, but shortcomings of design and construction. Gives two tables showing slight variations between two systems of figuring requirements, one based air change and other on exposed walls and glazed surfaces. Part II of series. L. A. BRISSETTE, *Architectural Forum*, 4-22, 2600 w. CS.

Housing in American Tropics. Demand for American building materials, housing plans, "readi-cut" houses increasing in Tropics. Special planning needed to expand business. Designs must take into consideration climate, sun, rain, pests of various sorts. Substantial building materials avoided in Latin countries because of earthquake. In new construction, following two methods of fighting

earth shock used: In one, frame is made elastic as possible, pressed steel or light stucco employed for wall sheathing and roofs made of galvanized iron or some material which may be well secured and light. Other method employs monolithic base, so that building cannot be subjected to strains, and if moved, will move as unit. WILLIAM P. COMSTOCK, *Architecture and Building*, 3-22, 1800 w. HHH.

Knickerbocker Theater Disaster. Complete report of investigating committee appointed by the Associated General Contractors, Inc., of America. Contains 14 illustrations and concise review of all other reports previously made as well as reasons advanced by well-known engineers. The reason given for the failure is negligence on the part of the men responsible and faulty detailing which was made possible by such negligence. *American Architect*, 4-26-22, 1200 w. EMCC.

Cost of a Home. Cost in 1914, 1920 (peak of high prices) and March, 1922, of three types of houses. Cost is given by square feet of floor area, by cubic feet contents and total cost. Type A is a 2-story frame house with 7 rooms; Type B is a 2-story Colonial frame house with 8 rooms; Type C is a 2-story shingle house with 8 small rooms. The 1914 cost being 100%, the 1920 (peak) cost was, respectively, 231%, 233% and 232%, the March, 1922, costs being, respectively 171%, 176% and 172%. *Chem. Bulletin*, 3-22, 1000 w. EMCC.

Chinoiserie in English Decoration. Comprehensive, well illustrated article on use of Chinese motifs in furniture design. Give airy brightness in decoration. Entire rooms furnished in this design generally unwise, but when used within bounds of good taste, style holds forth many delightful possibilities attained in no other way. WALTER F. WHEELER, *Architectural Forum*, 4-22, 2200 w. CS.

Determination of Ground Rent. How two courts interpreted lease of Spokane land calling for 5% of value of land exclusive of improvements. Case brings out interesting principles of appraising. *Buildings & Building Management*, 4-3-22, 1500 w. CS.

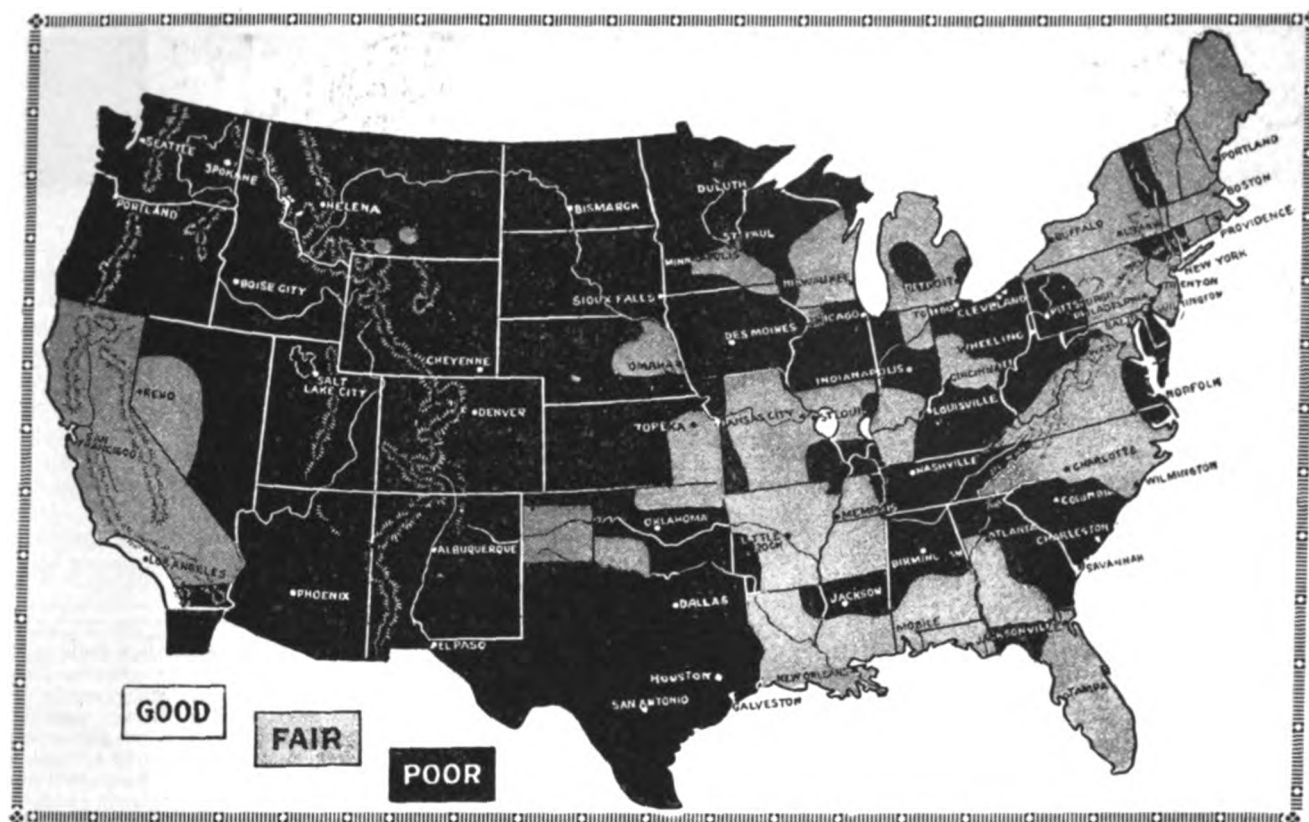

Analysis of Construction Costs and Methods. Part XIV. Explaining functions of material control system, use, and giving simple forms adapted to all size shops. HARVEY A. CALL, *Sanitary & Heating Eng.*, 4-7-22, 3000 w. CS.

Community Buildings for Industrial Towns. Illustrated article showing examples of basement, first and second floor plans of community buildings costing from \$160,000 to \$250,000. MARTHA CANDLER, *American Architect*, 4-12-22, 4000 w. EMCC.

Curved Pile and Rock Breakwater Built in Deep Water. Description of breakwater built on curved lines in deep water at Chicago, and methods of surveying. *Eng. News-Record*, 3-30-22, 900 w. CS.

Small Units in House Building. Third article of series, dealing with floors, sills and lintels, illustrated. A. J. R. CURTIS, *Concrete*, 3-22, 2000 w. CS.

Business Conditions, April 1922

The map shows at a glance the general conditions of the country. Light areas indicate good crops, industrial activity, and "high pressure" buying markets. In the black areas these conditions are lacking. The shaded areas are half way. In studying the map it should always be borne in mind that only actual conditions are shown; prospects are not indicated.

(The Douglas Map, from *Nation's Business*)

Law and Architecture. Discussion by a member of the New York Bar on the extent to which an architect may delegate authority to others. Conclusion reached is that a conservative course should be followed and only such authority should be delegated as cannot be questioned. Advises special clause in contract to meet needs whenever it appears that some delegation of authority may be necessary or advisable. CLINTON H. BLAKE, JR., *American Architect*, 4-12-22, 1000 W. EMCC.

Structural Details. An illustrated article on developments in building design. Gives examples of details used for articulation between reinforced concrete and structural steel members in recent important buildings. Beams seated on multiple seats and columns resting on spirally reinforced bases, with weak columns reinforced by means of reinforced concrete fireproofing. ELWYN E. SEELYE, *American Architect*, 4-12-22, 1500 W. EMCC.

Further Simplification of Paving Brick Varieties. Four months ago there were 66 varieties of paving brick; today there are only seven recognized types and sizes. This elimination results in co-operation between government, manufacturers, associations and engineers. *Municipal & County Eng.*, 4-22, 500 W. CS.

Education for Architects. Retrospective view of architectural education by a man who studied architecture in schools but deserted the profession because architects are forced to be realists and teachers of architecture are romanticists. To the former he says a brick is a thing

that enters into the construction of a building; to the latter it is a symbolic pattern of ruled lines sometimes covered with a pinkish wash. MERRILL DENISON, *American Architect*, 4-12-22, 2500 W. EMCC.

Plumbing and Drainage Plans. Graphical presentation of the requirements of the New York City plumbing and drainage code. In this diagram a 13-story building is shown fully equipped with plumbing and sanitary apparatus. Numbered circles refer to the appropriate sections of the code dealing with each bit of equipment shown. B. HOFFMAN, *American Architect*, 4-12-22, 700 W. EMCC.

Putting Business Methods Into State Highway Management. For two years

Pennsylvania has led all states in mileage of paved roads. During 1921 spent \$35,000,000 for new construction and \$10,000,000 for maintenance. Has built up excellent management division to coordinate work. Principal features are: Complete graphic records, close financial control, promotion on performance, square deal to contractors, developed teamwork, intimate data on personnel, uniformity in office practice. Completed described. *Eng. News-Record*, 4-6-22, 3500 W. CS.

Standardization in the Building Industry. Address of government official at convention National Association of Builders' Exchanges. Covers: Lack of standardization; elimination of varieties; standardization cut stone, brick, lumber and other basic materials; establishing standards of work; cost accounting; forms of contracts; why every group should be interested in simplification. JOHN M. GRIES, *Cons. Economics Ed., Amer. Cont.*, 2-25-22, 5000 W. CS.

CEMENT·STONE·BRICK

Good Outlook for Brick Manufacturers

ACCORDING to the *American Contractor* an increased interest in brick construction is evident throughout the country. Orders are increasing, and the stock of burned bricks on hand is smaller than it has been for months. In the Chicago district, which is the largest brick-producing centre in the world, the deliveries of brick through the months of February and March were at a rate that promises a season's output closer to normal than has been experienced in the past two years. In other large centres the demand is above normal for this season of the year. What is most important, however, is the fact that in the agricultural States there is a most encouraging revival of building. Due to the publicity given to brick by the American Face Brick Asso-

ciation, manufacturers are hopeful of securing nearer a just proportion of the construction business than before.

Judging from various reports published by the Government and by statistical agencies, it would appear that it is safe for financial institutions to loan upon construction today upon the same percentage basis as in 1913. It does not seem likely that marked reduction will take place in the cost of basic materials for several years. Those commodities in which labor and transportation are the largest factors show the higher index. In the manufacture of common brick there has been practically no change in the cost of raw material; consequently the current price reflects to a large degree labor and transportation costs.

Placing 410,000 Cu. Yds. of Concrete on Ontario's Niagara Power Development. Part I. Covers plant layout for mixing and placing concrete for powerhouse, forebay and lining 9-mile Queens ton-Chippawa Canal. With design and testing of mixture to meet prescribed strengths. Well illustrated. A. C. D. BLANCHARD and R. B. YOUNG, *Eng. News-Record*, 4-6-22, 5500 w. CS.

Vital Facts on Portland Cement. Gives history of cement industry, built up in 50 years on basis of high service and constantly declining prices. Tells how competition among manufacturers operates. Interesting article, in view of claims made that manufacturers have been charging exorbitant prices. JOHN E. McELDOWNY, *Highway Engineer & Contractor*, 4-22, 4000 w. CS.

Reviving Color of Marble. Use of decorative colored marbles limited in United States by climate. Various methods tried to preserve pristine beauty of marble for outside use by application waterproofing compounds; but little attention paid to study of chemical changes underlying fading, with object of arresting these changes. Results of French tests given, using milk of lime. *Stone*, 4-22, 1100 w. CS.

Central-Plant-Mixed Concrete Tested for Maximum Safe Haul. Results of tests to determine maximum length of haul show that concrete could be handled by pavement finishing machine up to 2 hrs. after mixing. Too hard after 45 min. for hand finishing. As long as concrete is workable after period of hauling, strength is not affected. *Highway Engineer & Contractor*, 3-22, 800 w. CS.

Lightweight Concrete Tile the Latest Development in Products Field. Résumé of lightweight building tile. Illustrated. Gives description of various standard shapes, weights, construction, costs. *Permanent Builder*, 3-22, 2000 w. CS.

Details of Cut-Stone Work. Suggestions for detailing stone work prepared by Indiana Limestone Quarrymen's Association. Factors for preventing of stain are: prevent direct contact with cement

and prevent moisture from passing through walls. Other points covered: waterproof course at grade level, steps, platforms, column and pilaster bases, columns, pilasters. *Stone*, 4-22, 1500 w. CS.

Steel Rib Reinforcement Used for Concrete Arch Centers. Structural steel arch-rib reinforcement used on monumental concrete bridge across Connecticut River at Springfield, Mass. These serve as centering for arch ribs during placing. Complete details of design and construction given, illustrated. *Eng. News-Record*, 3-30-32, 4000 w. CS.

Concrete Docks Defy Tornado. Gives details construction and costs concrete docks in Pierce County, California, and for Atlantic Coast Line Railway near Panama Park, Florida. First cost about three times wooden-pile structure. *Eng. World*, 4-22, 2000 w. CS.

Effects of Moisture on Behavior of Concrete. Results of tests at University of Illinois. Covers: Purposes and methods of tests, effect on length of specimens, rates of absorption and expansion, and final conclusions. *Eng. News-Record*, 3-30-22, 2000 w. CS.

Concrete Dam 22 Feet High Built with Traveling Form. In constructing concrete spillway for new water supply of Danville, Ill., timber frame spanning site and riding on rails on foundation carried steel spillway form by adjustable rods. Steel form 20-ft. long, built up plates and angles, with holes in plates to make tie rods adjustable. *Eng. News-Record*, 3-16-22, 500 w. CS.

Ideas on Quarry Blasting. Drilling and blasting are so interdependent that consideration of one would be incomplete without study of other. Very comprehensive article dealing with various quarry conditions and various explosives used. N. S. GREENSFELDER, *Pit & Quarry*, 3-22, 1800 w. CS.

Concrete Products Plant Operation. Report of Committee P-6 of American Concrete Institute. Covers complete details of design, construction, operation and sales. *Concrete Products*, 4-22, 3300 w. CS.

CLOTHING GARMENTS

Brighter Prospects in Clothing Industry

THE most important development in the clothing industry during the last few weeks has been the Chicago wage adjustment, which, it is believed, will furnish a basis for adjustments at other centres along similar lines. It is estimated that the wage reductions put into effect in Chicago will result in a saving of about two dollars a suit. If this saving could be stretched to five dollars, a considerable increase in business would be almost certain to result. According to *Manufacturing Clothier*, the indications now are that re-ordering by the retailer in the fall will be prompt, well distributed, and of good volume. Although no exact figures are available, retailers' stocks of garments are said to be low, and it is reported that fall lines of suiting and overcoats

now being shown to the retailer are ten to fifteen per cent below last year in many cases.

Sellers of men's wear fabrics are in a more cheerful frame of mind than they have been for some time. While the Chicago wage agreement is largely responsible for their attitude, other influences which have brought this about are: the entrance of tailors-to-the-trade into the market; the expectation that clothiers' business with the retailer in fall garments will induce reorders for cloth; the absence of overproduction in primary circles; the cessation of the upward swing in the raw wool market; and the belief that a settlement of the tariff question is near at hand. The textile strike introduces a factor of uncertainty into the situation.

Exclusive Agencies. The policy of restricting or confining goods to certain selected retail outlets helps the retailer by: (1) Giving him prestige; (2) giving him the benefit of the general advertising of the manufacturer; (3) securing him against competition in the restricted line; (4) securing him ready-made, pulling ads and other sales-helps. It may harm the retailer by: (1) Lessening his advertising and business initiative; (2) laying him open to chain-store competition in the restricted line. It helps the manufacturer by: (1) Keeping his goods out of price wars; (2) cutting down sales of sub-

stitutes. It may harm the manufacturer by: (1) Reducing his opportunity for selling. A. O. BAUMGARDT, *American Hatler*, 4-22, 1800 w. WRB.

How to Apportion Advertising Appropriations. Seventy-five per cent to newspapers; circulars 15%; dodgers and posters 5%, and remaining 5% to "hope chest," meaning good-will mediums like programs, college papers and the like. *Haberdasher*, 4-22, 1300 w. WRB.

Sporting Goods as a Sideline. Haberdashers in cities of from 10,000 to 50,000 population will be sure to make a success of handling sporting goods as

a sideline, largely because they will not have the local competition of the big specialty houses of the larger cities. For \$500 a dealer can carry a fair line of golf and tennis equipment. Sets of equipment are suggested. *ARTHUR BEAUMONT, Haberdasher*, 4-22, 1500 w. WRB.

How to Install a Mail-Order System. First step is to let public know of the service through advertising. How to check up on mediums for maximum service. The use of folders and dodgers, catalogs, card index system for follow-up. *Haberdasher*, 4-22, 1200 w. WRB.

Correct Dress Chart for Men

(Copyright by The Haberdasher, New York)

DRUGS CHEMICALS

Stronger Demand for Chemicals

THE optimistic attitude that exists throughout the chemical trade is believed to be the forerunner of a permanent improvement in business conditions. Just as price movements of railroad and industrial stocks are regarded as barometers in the securities market, so in chemicals, caustic soda is the barometer. And the demand for this chemical is now stronger than it has been at any time this year.

According to the *Chemical Color and Oil Record* inquiries for caustic have been coming into the market from Italy, Germany, Japan, China, and South America in sufficient

volume to absorb the output. America is today producing caustic soda at a lower price than any foreign country, and therefore seems assured of a steady influx of foreign orders.

Confidence is also expanding among domestic buyers. Carlot orders are becoming more numerous, and the danger of operating without carrying supplies to meet emergencies is becoming more fully realized by domestic consumers. The current price movements of chloride of barium, carbonate of barium, prussiate of potash and menthol are likely to convince cautious buyers of the advisability of purchasing stocks in advance of actual demand.

Oil of Wormseed. Producers of oil of wormseed, U. S. P., favor change in requirements of this oil, asking for lowering of minimum limit for specific gravity. This does not seem to be warranted. Oil can be produced that will meet all U. S. P. requirements by distilling herb with large volume of steam during relatively short period of time. With apparatus now in use, not less than 20 lb. of steam per min. should be passed through retort and distillation time should not exceed 15 min. "Warming up" of charge to be distilled is not necessary but is rather bad practice and water should not be added to retorts. Change in present distilling outfits can be effected at small cost and without complicating routine of distillation whatever. G. A. RUSSELL, *J. Am. Pharmaceutical Assn.*, 4-22, 3500 w. CJW.

Production of Hydrogen. Generation of hydrogen by the "silicob" process is described. Non-combustibility of materials used (silicon and sodium hydroxide) insures safety of transportation. Rate of reaction of ferrosilicon with sodium hydroxide, in subsequent generation of hydrogen, depends upon composition of material, its fineness, concentration of sodium hydroxide, and dissolved silicon in solution, as well as temperature. Plant, of small size, low cost and high productive capacity, consists essentially of 3 parts: solution tank, generator and washer. Merits of process and comparative cost figures for materials are given. E. R. WEAVER, *Trans. Am. Electrochem. Soc., Preprint*, 10 pp. (1922). CJW.

Turbidity in Varnishes. Tests made to determine causes of cloudy varnishes. Various driers were used, three lead resins of varying lead content and manganese resinate. Three grades of rosin were used in making the lead driers. Manganese drier was made with dark rosin. Temperature and time of heating were varied. Determined that temperature had no effect on the clouding of the varnish. In every case when lead resinate was used as drier varnish clouded up. Character of rosin did not matter. Manganese drier did not produce turbidity in varnish in any case. Lead is controlling feature of phenomenon. Deposit separated and analyzed showed large proportion of lead, while

examination of organic constituents revealed the presence of stearic acid in a predominating proportion. Concluded that turbidity is due to formation of lead stearate. Further experiments indicated that formation of the turbid deposit in varnish is connected with colloidal phenomena. Preventive methods must depend on treatment of oil. When linseed oil is heated to high temperature and the mucic acid contained therein separated by filtration, a varnish made from this oil will become turbid very easily. Mucic acid in oil prevents deposition of fine colloidal sediment, but keeps it in state of colloidal suspension wherein its presence is not indicated by physical appearance of varnish. Mucic acid is colloid protector, and to have varnish remain clear, it is not advisable to remove acid from linseed oil. P. O. SCRIBE, *Paint Oil and Chemical Rev.*, 4-5-22, 1200 w. IG.

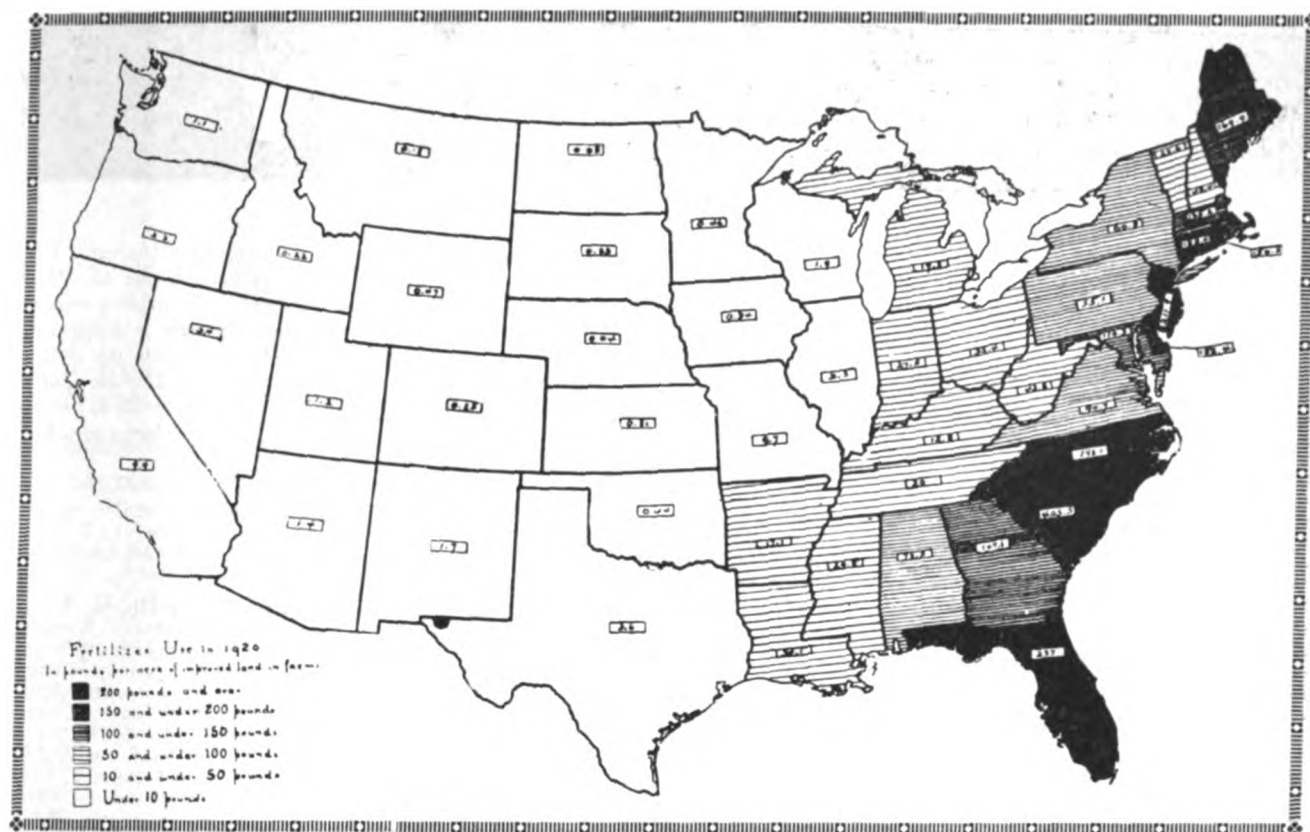

History of Words Pharmacy and Apothecary. Interesting article tracing the history and meaning of these words from the Greek to the 18th century. C. H. FIALON, *Am. Druggist*, 4-22, 1600 w. CJW.

Marketing of Pyrites. Pyrites covers pyrite, marcasite, and pyrrhotite with accessory sulfide and other minerals in greater or less amount. Raw material for manufacture of sulfuric acid for fertilizer trade. Important consuming localities for foreign pyrite are on or close to Atlantic seaboard. Chief marketing point is New York City. Competition mainly between domestic and foreign pyrites and brimstone. Two kinds are recognized on market, "furnace ore" or lump and fines. Always shipped in bulk, frequently as ballast. Prices range from 12 to 14 cents per unit (22.4 pounds sulfur). Suggested form of contract given. G. J. YOUNG, *Eng. Min. J. Press*, 4-8-22, 2000 w. CJW.

Sulfur Content in Oxide. After discussing eight methods, following is proposed as practical working method: Ten grams of dried spent oxide are extracted with carbon disulfide until extract is colorless. The solvent is then removed, alkali added, the mixture digested for an hour and the shiosulfate which is formed is weighed after oxidizing with bromine water and precipitating with barium chloride as barium sulfate. Volumetric method not recommended. C. E. LITTLE, *Gas Age-Record*, 4-15-22, 2000 w. CJW.

Centrifugal Clarifiers for Varnish and Gums. Design of certain types of centrifugal machines which give great super-centrifugal force. Treatment of varnish by means of this machine resulted in rapid aging of the same. This method can be used where solids are either heavier or lighter than the liquid. Considerable economy is effected by the method of centrifugal clarifying. A. H. KEABLE, *Paint, Oil and Chem. R.*, 4-26-22, 1800 w. IG.

Detonating and Priming Mixtures. Methods of analysis are given, intended for use in practical work and not intended to fill requirements of research worker on particular compound. Do cover need of chemist analyzing explosive compositions and desirous of results that are accurate within limits of variation of mixtures themselves. C. A. TAYLOR and W. H. RINKENBACH, *Bureau of Mines*, Technical Paper No. 282 (1922), 32 pp. CJW.

Fertilizer Use in 1920

The map shows graphically for each of the States the average use of fertilizer in the year 1920 per acre of improved land in farms.

(From *Cement, Mill & Quarry*)

Resorcinol. New method of manufacture consists in preparing benzene disulfonic acid by treatment of benzene with fuming sulfuric acid in two steps, neutralizing with lime, filtering off calcium zation, addition of molten sodium hy-zene disulfonate, evaporation to crystallization, addition of molten sodium hydroxide in proper quantity and heating at 315° C. for 2 hrs. When dissolved, sodium sulfite crystallizes out on cooling. Filtered solution carefully neutralized with sulfuric acid, and resorcinol separated by extraction with suitable solvent or by distillation. HARRY McCORMACK, U. S. Patent 1,406,745, Feb. 14, 1922. *Am. Dyestuff Reporter*, 4-24-22, 1000 w. CJW.

Drugs in Internal Medicine. Available drugs are of real value in curing, in ameliorating and in preventing disease, and new drugs are steadily being discovered that are useful. Introduction of new therapeutic methods and new drugs can scarcely be expected from now on to be arrived at by accident or through pure empiricism. Every new agent should be thoroughly tested in laboratory as regards activity and its dangers, and later in organized clinics, before it is introduced into general medical clinics. L. F. BARKER, *J. Am. Pharmaceutical Assn.*, 4-22, 3000 w. CJW.

Aromatic Elixir. Following formulas are submitted: Soluble compound spirit of orange: Oil of orange, terpeneless, 6.00 cc.; oil of lemon, terpeneless, 3.00 cc.; anethol, 4.00 cc.; oil of coriander, 12.00 cc.; alcohol, 5.40 cc.; distilled water, each, a sufficient quantity; purified talc,

15.00 gm.; to make 1000.00 cc. Dissolve oils and anethol in alcohol and add sufficient distilled water to make required quantity. Add purified talc and shake well for several minutes. Set aside for several days, shaking it frequently. Filter through paper in well-covered funnel, and wash filter with sufficient diluted alcohol to obtain required yield. Aromatic elixir: Soluble compound spirit of orange, 30 cc.; alcohol, 240 cc.; syrup, 375 cc.; distilled water, a sufficient quantity to make 1000 cc, 32 fluid ounces. Mix soluble compound spirit of orange with alcohol, add syrup and then sufficient distilled water to make required yield. E. R. JONES, *J. Am. Pharmaceutical Assn.*, 4-22, 750 w. CJW.

Volatile Oils in Pills. Sodium stearate is best for absorbing volatile oils. Soap from strongly hardened cottonseed oil would be better. Best material for stiffening soft soap and oil mass is fibrous material, such as powdered quassia wood. Peculiar property of soap absorbing oil is probably infiltration of oil into particles of soap and its absorption by the curd fibres of which soap largely consists. H. G. GREENISH and C. E. PEARSON, *J. Am. Pharmaceutical Assn.*, 4-22, 2500 w. CJW.

Chemical Manufacturing. First of series of articles discussing non-technical departments, their shortcomings and the usefulness of technical man in these fields. Theoretical organization usually divided into 8 departments: research and development, operating, engineering (maintenance and construction), purchasing, sales and credit, advertising, accounting and finance. Non-technical work considered more important to an organization than technical work. Strength and weakness of organization discussed. Work of purchasing department. Must know—specifications, consumption, markets and transportation. Technical brains needed in this department. C. WADSWORTH, 3d., *Chem. Met. Eng.*, 4-12-22, 3000 w. CJW.

Ammonia Catalysts. This article consists of description of apparatus used for testing ammonia catalysts under varying conditions of pressure, temperature, space velocity and purity of gas. Results will be given in later article. A. T. LARSON and A. P. BROOKS, *Chem. Met. Eng.*, 3-22-22, 3500 w. CJW.

Tips from an Expert on Spray Painting. How to use the machine effectively and economically. The importance of spray painting is emphasized. C. B. LYONS, *Paint, Oil and Chem. R.*, 4-26-22, 1200 w. IG.

Chlorine Control in Bleaching Cotton Goods. Discussion of Wallace and Tierman control equipment for preparation of sodium hypochlorite solution. Saving in cost of soda ash is considerable. Valuable feature is flexibility of operation. C. M. E. SCHROEDER, *Am Dyestuff Reporter*, 4-24-22, 1000 w. CJW.

ELECTRICITY

Steam Turbine Electric Locomotive

A NEW type of locomotive has been introduced into England, on the London and Northwestern Railroad. The forward part of this locomotive, where the steam is generated in the regular type of coal-fired boiler, looks just like the ordinary engine seen on American railroads, but the hind part of the tender differs considerably. Contrary to the method employed in driving the regular type, the new machine possesses both forward, rear and tender drive.

The locomotive is provided with a steam turbine which

drives a dynamo and produces a three-phase current. The latter is fed to two sets of induction motors, one of which drives the tender wheels and the other the locomotive wheels. The steam from the turbines goes through a condenser, where it is condensed by air, which is sucked into the system by means of a large fan located at the very end of the tender and which is blown through the bank of tubes. Each one of the four motors has a rating of 275 hp. The locomotive has a pulling power of 10,000 kilograms.

Electric-heated Steam Boilers. General Electric Co. has developed heating equipment and automatic control which may be applied to standard fire tube boilers. Require very little floor space, no brick setting, no stack, no attendance except occasional observation, and can be located at most convenient and advantageous point. Cost of fuel is equal when cost of in kw. hr. is equal to cost of 0.5 pound of coal or electric energy at 0.5 cent per kw. hr. is equal to coal at \$20 per ton. One boiler hp. is equal to 10 kw. hr. of electric energy. Control of steam pressure is accomplished by standard damper regulator. Automatic water feeder and water gauge with alarm features should also be installed. *Paper Mill*, 4-22-22, 750 w. CJW.

House Wiring Problems. Report of sub-committee of the N.E.L.A. Wiring Committee on four proposed classifications of houses on the basis of wiring for electricity. 1st. Electric service in the house means service, meter and one or two lights. 2nd. Electric service in each room means one light in each room. 3rd. A wired house means not less than

two outlets in any room and an average of three outlets per room. 4th. A well-wired house means not less than two outlets in any room and an average of five outlets per room. The committee also recommends the use of three 1500-watt circuits using 15-ampere fuses for residences having a floor area not exceeding 2500 sq. ft. and lists the rooms to be served by each circuit. Outlets to be installed with reference to convenience rather than a definite number per circuit. A discussion of this report is desired from architects and others interested in the subject of adequate wiring. *American Architect*, 4-26-22, 1000 w. EMCC.

Selling Electric Light as an Advertising Medium. Reasons are given why the contractor dealer need not fear a decline in his electric-sign business. Higher intensities of illumination are constantly increasing in favor. *Jour. of Electricity and Western Industry*, 4-22, 2000 w. IG.

Value of Service as an Element in Rate Making. The application of the service-at-cost theory is decreased in proportion to the essentiality of public utility ser-

vice and must be abandoned if it unduly restricts the use of service. *L. E. GETTLE, Electric Railway J.*, 4-1-22, 500 w. IG.

Electrical Wiring for Architects. Architects must give more attention. A recent survey of New York apartment house showed that tenants were using 157 large electrical utilities, such as vacuum cleaners, flat irons, etc., in addition to numbers of dining-table and toilet electrical appliances. Appliance load was 37.2%, power load, 34.4%, and lighting load, which alone had been considered when the house was wired, was only 28.4% of total. *American Architect*, 4-26-22. EMCC.

Horn Gap Switch. Description of new type of manually operated non-automatic single-throw horn gap switch for outdoor service. Some of its outstanding features are simple, but rugged construction, limited number of parts, non-freezing, positive in action, easy operation, quick opening, self-aligning and easily adjusted contacts, interchangeability of parts and ease of installation. *Central Station*, 4-22, 1500 w. IG.

Indicating Total Power from Several Generating Stations. How load dispatcher at a central point distributes the load on the line between several generating stations that supply the common line. Method of indicating the total power at this observation station to remove the personal error involved in telephoning. *H. P. SPARKES, Electric J.*, 4-29, 5500 w. IG.

Electrical Installation. Description of Efrd mill No. 5, Albemarle, N. C. Spinning mill unit of 11,520 spindles. Equipment produces greatest tangible returns under particular conditions of operation. Details of lighting, motor drives and wiring. *C. L. EMERSON, Textile World*, 4-1-22, 4200 w. WRR.

Laying Your Lines for New Business. A description of methods used in general merchandising of securing new customers and its applicability to the selling of current-consuming devices by central stations. At the present time the location of business is important. *R. A. HARDY, The Central Station*, 4-22, 3000 w. IG.

"The Voice with the Smile Wins." How a girl operator tried to convince telephone subscribers of this fact and the results. *Telephony*, 4-15-22, 4000 w. IG.

World's Greatest Steam Powered Electric Plant

Another German "greatest." The smokestacks, each 300 feet high, rise from the power plant which supplies Berlin with current. Fifty-four great steam boilers are in continual use, besides eight steam turbines of 20,000 horsepower each.

(© International)

EFFECTIVE STREET LIGHTING CHECKS CRIME

The difference in size of the two thugs indicates the 41 percent decrease in nocturnal street crimes effected by high intensity white way lighting in Cleveland

(From Public Service Management)

New Communication System for Power Stations. Application of the "carrier current" system of telephony as an effective means of communication between generating stations and distribution centers. Power equipment consists of a double current generator direct connected to either a 110-volt direct current or alternating current motor, which is equipped with suitable starting equipment and control apparatus. The high frequency current is modulated at audio frequency by the voice through a vacuum tube set consisting of an oscillator and modulator. It is then transferred to the transmission line by a capacitive coupling and drawn off at the other end by means of suitable detecting and amplifying apparatus. Receiving apparatus consists of a tuning unit and a vacuum tube unit. Tuner is used to tune the system to the frequency of the incoming signals and the tube unit to rectify and amplify the signals. Other details are given of this new system, which was tested out for the first time in public a few months ago. B. S. BEACH, *Central Station*, 4-22, 1500 w. IG.

Lighting Fixture Is a Luminaire. Recent action of the Council of the Illuminating Engineering Society agrees "luminaire" will hereafter be employed by all illuminating engineers and salesmen of lighting service. For a long time "lighting unit" has been felt to be awkward, while at the same time liable to be misunderstood by those who use the word "unit" to indicate a standard. "Removable fixtures" and "movable fixtures" are misnomers, for a fixture is supposed to be stationary or fixed. The word "luminaire," long used in France, covers all cases. *American Architect*, 4-26-22. EMCC.

Electricity in the House. This third article discusses proper wiring of a dining-room. Argument is based on the servant problem and the many electrical conveniences now on the market. M. O. WHITTEN, *Amer. Architect*, 3-29-22, 2000 w. E. McC.

Electricity in Paper Industry. Advantages are summed up as follows: Centralization of power generating and distributing equipment. Two or more generating units may be installed, preventing complete shut down in case of trouble. Power from several small developments may be combined. Manufacturer's plant

may be placed in most advantageous position, irrespective of location of power plant. Mill buildings may be arranged without reference to power supply. Elimination of unnecessary line shafting and belting. Equipment may be operated to secure maximum production with minimum power consumption. Cleaner, better and more uniform product is result. R. W. LEEPER, *Pulp Paper Mag.*, Canada, 3-30-22, 2500 w. CJW.

Features of Interior Winding. Discussion of underground entrances, safe carrying capacities, switches and cut-outs. *Electrical South*, 4-22, 4000 w. IG.

Radio Opens New Merchandising Field. The conditions in the radio industry are discussed. The merchandising features of the business are described. According to the writer's opinion, the future of the industry is very bright. *Class*, 4-22, 2000 w. IG.

THE WORLD'S TELEPHONES

(Public Service Management)

Electrification of Old Anthracite Mine. Description of method used for electrification of old mine, in which plans were so laid that as much of each of old steam-driven machines would be used as existing conditions would permit. No single complete electric hoist was purchased. Improved service resulted. W. H. LESSER, *Coal Age*, 4-6-22, 800 w. CJW.

Costs of Electrical Energy in California Compared with Ontario. Public utilities in California are making energy available to their consumers at a cost far less than in Ontario when differences in taxes and physical difficulties are taken into consideration. R. SIBLEY, *Jour. of Electricity and Western Industry*, 4-22, 3500 w. IG.

Better Lighting an Economy Measure. Shown that gain in shop production due

to installation of improved lighting system is much greater than increased cost of lighting. In case where exacting and very accurate work is carried out improvement was seen to be greatest. W. HARRISON, *Iron Age*, 4-6-22, 1400 w. IG.

Electricity in the House. This fourth article in series deals with wiring of modern kitchen, or food laboratory as it is to be called in the future. Recommendations for numbers of outlets are liberal in view of increasing use of electrical appliances caused by shortage of domestics. MARY ORMSBEE WHITTON, *American Architect*, 4-12-22. EMCC.

Unit Switch Control on Frankford Elevated. Cars used on this railroad in Philadelphia are described as well as the control system. Details are given to show how the operation of the car is controlled and how the motorman receives his signal. A sketch of the circuits in the train is shown. S. B. SCHENCK, *Electric J.*, 4-22, 5500 w. IG.

Electrical Cables for Coal Mines. Discussion by machine and cable manufacturers, coal operators and Bureau of Mines' engineers of size of conductor, flexibility of conductor, covering of conductor, layout of multiple circuit conductor, protection of terminal ends of cables, protection of cables from short circuits, inspection of cables, renewal of cables, and approved equipment. Large cables were advocated. All trailing cable should be protected by fuse. L. C. LESLEY, *Coal Trade Bull.*, 3-16-22, 1200 w. CJW.

Electric Motors in the Steel Plant. (Continued.) Electric motor braking as applied in a steel plant to restrict the speed of overhauling load to cause definite slow down and to stop. Various connections are shown. G. Fox, *Blast Furnace and Steel Plant*, 4-22, 3000 w. IG.

FUEL POWER

Fifteen Percent Proper Obsolescence Charge

WHILE a heavy allowance for obsolescence of machinery is necessary in every industry, in no other field is it more important than in coal mining. Like the automobile industry, mining grows old in two ways—in the product and in the machinery by which it is produced. When the product changes, the machine becomes obsolescent, even if the method of manufacturing the product remains up to date. The sizes of the coal produced change, the degree of cleaning desired varies, the need for power increases or decreases, and when the end sought changes, the means becomes obsolete perhaps even more rapidly than the machine.

In the opinion of *Coal Age* a fifteen percent obsolescence charge is justified. As an evidence of the progress in mining methods the following improvements are cited: the multivane fan, the electric hoist, the skip, the vibrating screen, the step-screen, the rotary dump, the cager, the trip-maker and feeder, the storage equipment, the safety hoisting devices, the loading boom, the improvement in box-car loaders, the car retarders

under the tippie, the picking table for cleaning each car individually, the sampler, the concentrating table, the thickener, the filter, the flotation cell, pulverizing equipment, the gravity separation tank, the air-jig, the storage battery locomotive, the combination locomotive, dynamite breaking retarding conveyor, the belt and apron conveyor for the product of one or several mines, the arc wall coal cutter, the unloading device for mining machines, the coal loaders, the heading machine, the room hoist, the cement gun, the portable compressed air machine, the coal and rock drills, the large stripping shovel, the air dump car, the electric safety lamp, the oxyacetylene and electric welders, the automatic starting devices, the automatic reclosing circuit breakers, the bearing thermostats, the centrifugal pump and a number of others.

The retention of old machinery invariably results in lowered output and more expensive operation, while new standards of production and increased profits are certain to follow the installation of new equipment.

Gasoline by Cracking Heavier Oils.

Evidence tends to support theory that cracking is contact-surface reaction, as controlling temperature is that of furnace walls rather than of current of oil vapor. Range of temperature favorable for commercial production of gasoline seems to be, for any given oil and pressure and rate of feed, within limits considerably less than 50 deg. C. apart. This is not same for all oils and seemed to be at least 20 deg. higher for Humble field, Tex., distillate than for Penn. gasoil. Pressure is favorable for cracking up to 200 pounds gage reading. Advantage of increasing pressure from atmospheric to 100 pounds gage reading is notably greater than by further increase to 200 pounds. Quantity of carbon formed for range of conditions favorable for gasoline production seems to be controlled chiefly by content of highboiling fractions, particularly so-called asphaltic by using properly prepared oils and by controlling temperatures. Single treatment in furnace will produce about 20 to 25 per cent yield of gasoline. Losses

in recovery of cracked oil range from 10 to 30 per cent (chiefly gas formation). Gasoline produced has relatively high degree of unsaturation, but this is not essentially disadvantageous in commercial utilization as motor fuel, if diolefins are removed. Specific gravity indicated 10 to 15 per cent aromatic hydrocarbons. Residuum from once-cracked oil does not seem to be quite as good for cracking as original oil. E. W. DEAN and W. A. JACOBS, *Bureau of Mines*, Tech. Paper No. 258, 56 pp. 1922.

Essentials of Successful Furnace Heating. Discussion of principles of air movement leading to correct design of ducts and registers. Where should cold air be taken from? Discussion of returns. R. W. MENK, *Sheet Steel Worker*, 3-31-22, 2000 w. APS.

Refrigeration Talks in Plain Language. Application of mechanical refrigeration to industry increases daily. Basic theories essential to power plant engineer. Basis of refrigeration, unit of heat and work, specific heat, thermometer scales—latent

and sensible heat, radiation, convection and conduction are discussed. T. H. FENNER, *Power House*, 4-5-22. AS.

Control of Gas Pressure by Distance Indication. Discussion of the importance of being able to control pressure along the line and description of an instrument that enables such control to be accomplished at a distance from where the pressure is indicated. Meter works upon an electrical principle. Meter body is located at point where measurements are desired. Pressure changes are recorded instantly. G. WEHRLE, *American Gas Jour.*, 4-8-22, 3000 w. IG.

Carburetion and Fuel Economy. Three essentials of correct carbureting system are: Metering of most economical air-fuel mixture at all loads and speeds; uniform distribution of this mixture at instant spark passes in cylinders; complete vaporization of all fuel at instant spark passes in cylinder. Study shows that carburetor engineers have hard problems in order to compensate carburetor so as to give usable mixture ratios throughout throttling range. Methods thus far employed ineffective. 3400 patents thus far listed by Lucke. Relations illustrated by curves. (To be con't.) J. N. GOLDEN, *Automotive Ind.*, 3-23-22, 2000 w. CJW.

Link-Belt Silent Chain Drives. Electrification of textile mills has led to the use of many individual electric motor installations, and this in turn has brought out the need for a flexible, powerful, dependable, quiet drive for which the silent chain has been found peculiarly suitable. This engineer describes a number of Link-belt silent chain installations in textile mill work. H. D. MITCHELL, *Jour. of Commerce (Canada)*, 3-17-22, 1800 w. MAH.

Elimination of Odor in Sewage Gases by Burning. Description of methods used at Austin, Texas, to eliminate odors from raw sewage and treatment plant by passing through furnace using gas from digestion tanks as fuel. C. E. LEONARD, *Eng. News-Record*, 4-6-22, 2000 w. CS.

(From The National Engineer)

Losses by Steam, Air and Water Leaks

From an inspection of this table, credited to the Chief Engineer of the Rock Island railroad, it will be seen that a few small leaks in a system will run up in large figures when allowed to continue for any length of time.

The Waste of a Ton of Coal. See Digest "Loss in Handling Coal," below.

(From Coal Age)

Loss in Handling Coal. Under average conditions of mining, transportation, combustion and conversion to power, every ton of coal stored by nature shrinks to incredibly small figure of 76 pounds in industrial plant; 1,211 pounds actually disappear at plant, without delivering any return; 631 pounds are lost at mine and 82 pounds in transportation. If best plant is paying \$5 per ton for its coal, average plant is, in effect, paying \$41.67 per ton. (Charts.) *Industrial Power*, 4-22, 800 w. CJW.

Steam Consumption of Soot Blowers. Outstanding feature of valve-in-head soot blower is steam saving effected by having unit valve open just long enough to have jets pass over port of tubes to be cleaned. With valve set for 300, head uses steam 5 to 7 seconds; blower revolves only 2 or 3 times. Steam used only 15 to 21 seconds per blowing. Valve of plain revolving soot blower necessarily open 45 to 60 seconds. Charts showing steam consumption ratios are given. *ROBERT JUNE, Power House*, 4-5-22, AS.

Piette Coke Oven. Characteristics are: Carbonization chamber and whole structure are perfectly tight. This permits extraction from coal of maximum of by-products. Short circuits in wall flues have been done away with through reunion, in 2 continuous series, of upward-

flame and downward-flame flues. Distribution of gas in each oven wall by several compartments fed by individual tuyeres, each supplying gas to 3 or 4 flues, permits regulation of quantity of gas admitted at every point of oven in such manner that it takes into account effect of taper and cooling from outside. Use of sliding brick unnecessary. Automatic regulation of temperature of combustion air assists materially in equalization of heating of several ovens in battery. Remarkable stability. Ovens easily operated and watched. Experimental plant operated at St. Louis. *Chem. Met. Eng.*, 4-26-22, 1500 w. CJW.

Oil-Water-Coal Gas. Process consists in injecting powdered coal, simultaneously with superheated steam, into long and high, but very narrow chamber whose main walls are kept at as high temperature as can be resisted by refractory materials of which chamber is built, varying from 2800° F. at bottom to 2400° F. at top. Gas efficiency of 64% to 66% is attained, but process does not recover by-products. *F. C. CORNET, Gas Age-Record*, 4-15-22, 750 w. CJW.

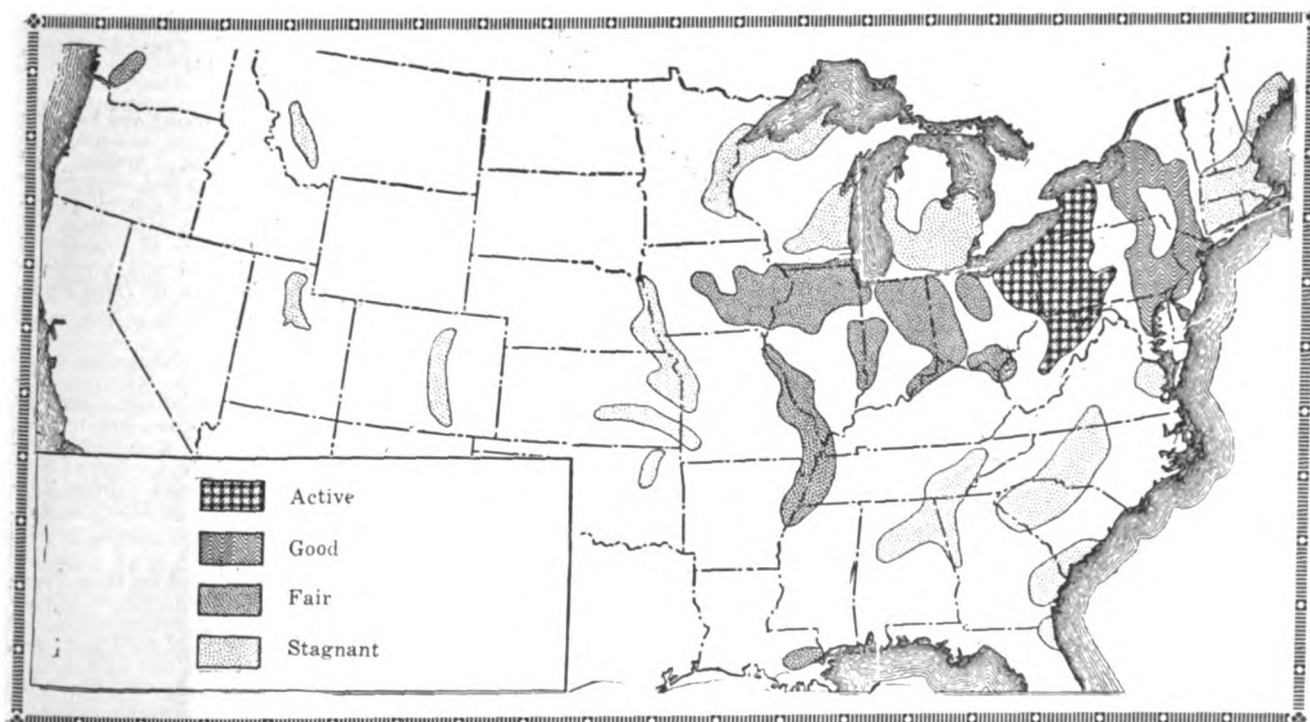

Separators in Steam Plant. Review of uses of separators and diagrams of a few types of horizontal and vertical separators. *W. H. WAKEMAN, Southern Eng.*, 4-22, AS.

Recovery of Coal from Ashes. Ashes or cinders contain large amount of unburned coal as such together with large percentage of coke. Upon grinding and flotation in Janney test machine using Barrett Salt Lake City heavy oil, and after agitating few minutes, adding little crude turpentine, results indicate that 100 tons of cinders would give 61.4 tons of recovered coal having ash content of 12.9 per cent, combustible content of 87.1 per cent, being 94.5 per cent of combustible matter contained in original cinders. Recovered coal can be burned as powdered fuel, mixed with slack or mine run or briquets. *W. D. GREEN, Chem. Met. Eng.*, 4-12-22, 500 w. CJW.

Decarbonizing Process. Apparatus for removing carbon must insure a constant flow of oxygen, must provide means for introducing oxygen jet into cylinder and must be able to quickly start and stop flow of oxygen. Present types of equipment are satisfactory. Gives rules for setting of pistons. *B. HEYMAN, Welding Eng.*, 4-22, 1000 w. APS.

Relative Activity of Markets for Bituminous Coal at End of Third Week of Strike

(From Coal Age)

IRON STEEL

Steel Mills Feeling Fuel Pinch

THE effect of the coal strike upon the iron and steel market in the past week has been evidenced by advancing pig iron prices and an increased demand for rolled products. Buying of steel has recently been stimulated by the inability of mills to make prompt deliveries, and consumers have found that they must lay in stocks instead of drawing on the mills week by week as they have done for months. While the steel mills had stored a sufficient supply of fuel for the production of steel at the rate it has been manufactured for the past few months, the recent increased demand for steel products as a result of the building boom has resulted in the consumption of much of the coal stored in anticipation of the strike.

The likelihood of a fuel shortage for the steel mills is still further increased by the fact that in the important coking fields of the Connellsville and Masontown, Pennsylvania, districts, the union miners have prevailed on the non-union men to join the strike, and reports from other non-union fields proclaim that the same tactics have been used with varying success elsewhere, particularly in Kentucky and West Virginia.

It is believed that if the strike in Pennsylvania continues, and maintains its hold in the other non-union and producing fields, there are grave possibilities that steel prices may increase, and that the output may be considerably below the requirements of the various industries.

Electrolytic Iron. Electrolyte is composed of ammonium and ferrous salts in water, containing 60 grams iron, 25 grams chlorine and 25 grams ammonia per liter. Must be acid in reaction. Necessary to filter continuously in order to keep impurities at minimum. Anodes must be as pure as possible and Bessemer or open-hearth steels can be used. Cathode starting sheets are made from cold-rolled steel riveted to copper bars. Cathodes receive 12 to 13 day deposit of iron and then are removed. Deposit, which is about $\frac{1}{4}$ inch thick, is stripped. Current density of between 12 and 15 amps. per sq. ft. of immersed cathode produces satisfactory results. Actual yield is approximately 90% of theoretical yield; 3300 amp. is used per tank at approximately 1.3 volts. Average output per kw. hour is approximately 1.5 lb. refined iron. G. F. McMAHON, *Chem. Met. Eng.*, 4-5-22, 2000 w. CJW.

New Reversing Valves for Open-Hearth Furnaces. The usual bell valve deteriorates rapidly, and as inspection is possible only during shut-downs of furnace it may operate defectively and inefficiently for a considerable time before the defect is detected. A new valve in which the above defects are remedied is made by the Mannstaedter Works at Troisdorf, near Cologne. The valve is made in two parts so that inspection can be made during working of furnace and the partition walls are protected from destructive action of the gases by cooling water. The Mannstaedter gas reversing valve is operated by hand or automatically by electricity, compressed air or high pressure water. HUBERT HERMANS, *Blast Furnace & Steel Plant*, 4-22, 1800 w. APS.

Stainless Steels and Cutlery. History of invention, specifications of steel, method of manufacture of steel and conversion into cutlery. Heat treatment and final tests on products. Photomicrographs and detailed discussion by members. R. G. HALL, *Trans. Amer. Soc. for Steel Treating*, 4-22, 5000 w. APS.

Composition of Steel-Standards. Standards Committee of the American Society for Steel Treating report showing necessity for numbering system by which

chemical analysis of steel may be indicated. Such system already established by Society of Automotive Engineers but scope has been extended to include wider range of steels of interest to the A.S.S.T. By means of these numbers, for which there is key showing grade, type, and carbon content, it is possible to classify steels closely. Instead of speaking of "tool steel," or even of tool steel containing a certain percentage of one important element, will be possible to give number indicating exact percentages of most important constituents. *Trans. Amer. Soc. for Steel Treating*, 4-22, APS.

Heating Time and Surface Relations. Study of relation of time for heating round sections to surface per pound of steel exposed. Expressed by graphs and formulas. E. J. JANITZKY, *Forging & Heat Treating*, 4-22, 2000 w. APS.

Development of Continuous Rolling Mills. Merchant mills are not well adapted to continuous principle, but can be designed so that material passes but once through each stand of rolls giving substantially continuous practice. Calculation of cooling bed surface and cooling bed length for given billet length. Question of employing a continuous mill is balancing low operating cost and high yield against large initial investment. See sketch below. JOHN W. SHEPHERDSON, *Iron Age*, 4-27-22, 2200w. APS.

Preliminary Study for a Continuous Merchant Mill for the Production of Rounds. See Digest Above.

Automatic Hot Billet Scraper. Mechanical device to replace air hammer and cold chisel in removing surface defects from billets in the rolling mill. Scraping mechanism is set up between two of the stands of rolls in the series and another is set immediately following the last stand of rolls. The advantages are set forth. Table of results showing increase in shippable output. The cost of knives is .3 to .5c per ton of billets. R. C. ROHRBACHER, *Iron Age*, 4-27-22, photographs, figures, 1000 w. APS.

Heat Treatment Not Always the Cause of Failure. This refers to dies, in the heat treating of which there are large losses. Author points out the importance of the fillet or rounded corner, the possibility of avoiding failure by a study of the shape from a heat treating standpoint and a subsequent change in the design, and others. Contains many practical pointers for practical tool designers. CHAS. A. BROOKS, *Can. Machinery*, 3-30-22, 1550 w. MAH.

Better Heating in Forging and Forming Practice. Necessity for uniform heating; importance of rate of heating. Fuel costs. Furnace design and arrangement of chambers and working openings and methods of heating and handling (41 figures) to meet nature of process and material to be heated and production requirements. *Forging & Heat Treating*, 4-22, APS.

Wire Drawing. Popular description of wire drawing process which is described as "an industrial epic penned by a master hand that knows how to paint an alluring picture of a seemingly prosaic subject without the sacrifice of technical accuracy and detail." JOHN KIMBERLY MUMFORD, *Raw Material*, 4-22, 4000 w. APS.

Ball Bearing Steel and Its Heat Treatment. Because of intermittent and repeated compressive deformations and rolling friction between balls and races, both great toughness and hardness are necessary. Chromium from .60 to 1.50 meets necessary conditions. Details of necessary heat treatments. CARL T. HEWITT, *Forging & Heat Treating*, 4-22, 1800 w. APS.

MACHINERY

Advisable to Purchase Machine Tools Now

THE necessity of reducing production costs in order to meet competition is well recognized in every industry. Efficiency experts are employed to eliminate waste motion in manufacturing processes, and labor saving machinery is installed wherever possible in order to reduce the number of employees. But in some cases the buying of new and improved machine tools is postponed until capacity production is reached, in the belief that by that time prices will be reduced to pre-war levels. But, according to *Canadian Machinery*, this is not likely to occur until transportation is as cheap as it was in 1914, wages as low, working hours as long, and taxes as moderate. And waiting for such a time can only result in sacrificing in production costs far more than the anticipated saving in price of equipment—in paying more for the machine you do without than for the one you buy.

If machine-tool users wait to order additional equipment

until capacity of present facilities is reached, the machine-tool industry must wait until after all other industries are in full swing. Then the machine-tool builders will be compelled to outbid their own customers for high priced labor and materials. Those manufacturers who invest in tools at a high first cost will be forced to compete with those who invested at a low price.

Secretary of Commerce Hoover has urged the railroads to purchase equipment now, because the low level of prices makes the equipment a better investment for the long pull, and because current orders stimulate all business and bring it that much nearer normal. A machine tool is a capital investment that stands ten or fifteen years. Such slow "turnover" produces the greatest returns if the investment is made when the user can get the best quality and when, because the builders' cost are lowest, the price is also low.

Increasing Output by Means of Turret Lathes. Multiple tools and attachments which shorten machine times, and thus reduce costs, are described and illustrated. Work time is much reduced by rugged character of these tools, and the heavy cuts and feeds which this permits, also by the fact that several operations are proceeding simultaneously, such as facing, boring and taper threading, turning, boring and facing, etc. J. H. RODGERS, *Can. Machinery*, 4-6-22, 1450 w. MAH.

Speeding Up Gauging of Threaded Work. The ring gauge is not an accurate measure of the screw or other piece of threaded work, in that it will pass a screw of bad form and low mechanical strength, perhaps as readily as one of good form and good strength. A more accurate tool is to be found in the Wickman adjustable thread caliper, with which all externally threaded parts may be inspected with absolute accuracy as to pitch, effective diameter, major and core diameters, and can be varied within any desired limits of accuracy. The article describes this British tool in detail, and its work, giving many examples of taps and screws inspected by it. *Can. Machinery*, 3-30-22, 3000 w. MAH.

Testing Accuracy of Gear Tooth Profiles. Their very nature makes the testing of gear tooth profiles and the spacing of teeth extremely difficult, yet it is important that these dimensions be checked very carefully. The methods of Pratt & Whitney are described and the apparatus which this firm has devised. This includes simple yet accurate methods of generating an involute, both mathematically and graphically. Use of the odontometer. H. ALTON, *Can. Machinery*, 3-23-22, 2400 w. MAH.

New Form of Tooth Gear. A new gear, called the Autopitch gear, has been developed abroad. Briefly it consists of the use of a number of laminations or thicknesses of material into which the teeth are cut. By arranging this laminated material around the axis of the gears, so that these laminations follow the direction of application of power, the cutting of shallow tooth forms results

in a modified roller action in that different parts of the tooth surface can yield differently, according to the character of the forces applied to them. This arrangement, according to the inventor, results in gears which have noiseless action, elasticity, economy of cost of production and power when in use, adaptability, durability and strength. W. RUS DARLING, *Can. Machinery*, 3-23-22, 6700 w. MAH.

Making Use of Tables. Author presents a number of quick methods of calculating, or short cuts in everyday arithmetic. He tells how to use tables of squares and cubes, also various ways to AYARS, *American Machinist*, 2-23-22, 1600 w. MAH.

Drill Sharpener Possibilities. Drill sharpener one of most economic shop

tools ever devised. Merely application of die forging. Heated steel placed in die, while dolly driven by air hammer upsets steel in die. Every bit that comes out of same die is exactly alike. Average rate about 4 to 6 per min. Tempering and heat treating is another step and best handled in specially designed furnaces. Examples given of applications. LETSON BALLIET, *Salt Lake Mining Rev.*, 3-30-22, 1000 w. CJW.

Organization of a Large Tool Division. The title describes the article exactly. The general outline of the organization is presented, functions of the various heads outlined, forms used for despatching work are described and illustrated, and to a limited extent the passage of the material through the division sketched out. H. P. LOSELY, *Machinery*, 4-22, 7600 w. MAH.

To Help Sixty-Thousand Families with Their Ironing
This mischievous looking giant spindle, here being lowered into the turbine cylinder, is to be devoted to peaceful arts. Steam under great pressure passes through blades, rotates the spindles and develops 40,000 horsepower of electricity.

GLASS · POTTERY

Window Glass Demand Dull, Plate Glass Better

ACCORDING to the *National Glass Budget*, window glass manufacturers and jobbers are at sea as to what is responsible for the lack of demand for window glass, particularly in view of the fact that there has never been a season at this time of year in which there was more construction work under way than this year. But whatever the cause, there is no indication of immediate improvement. Stocks in the hands of the jobbers and small dealers are very low, however, and it is expected that when buying finally

starts it will be very heavy. The manufacturers are ready.

In the plate glass industry, conditions are somewhat better. Present demand for plate glass is reported to be just about equal to production and factories are working well up to capacity. There is a slight increase in the amount of orders in evidence with a still further improvement anticipated. Importations of plate glass averages about a half million square feet per month. This glass is coming in on both the Pacific and Atlantic coasts.

American Gauge Glasses. Manufacture of gauge glasses practically an infant industry. Until recently European glass

manufacturers dominated market. England first made these glasses; Scotland and Germany followed. American man-

ufacturers, after years of experiments, are producing product of highest class. Venice supreme in art of glassmaking until about 1300. The first articles exported from this country to Europe were bottles, made near Jamestown, Va., in 1608. *Mill Supplies*, 4-22. AMC.

Distribution of Urban and Rural Dwellings by States

An analysis which shows that the number of country homes exceeds those in the cities. Following the analysis of home ownership throughout the United States as compiled by the Bureau of Housing under the Department of Commerce, which was published in the *Electrical World*, this comparison of the number of rural and urban dwellings is pertinent. The chart shows conditions which have considerable significance to the electrical industry. Of the forty-eight States only twelve have fewer rural than urban dwellings.

Action of Metallic Lead in Pots. Metallic lead in litharge always produces troubles in manufacture of lead glass. To determine how bad action of lead glass was, author incorporated quantity of fine granulated lead into a lead batch, replacing equal amount of litharge, which amounted to about 35% by weight of glass. New and carefully glazed pot, holding about 150 pounds of batch, used. Glass melt came down clear, and in as good condition as a filling made with litharge. Upon cleaning pot it was found there had been no action upon pot bottom and no trace of metallic lead was found. Under certain conditions, metallic lead is formed during the melting of batch and if there are crevices or holes in pot bottom lead button settles therein. *HENRY W. HESS, Glass Worker*, 4-8-22. AMC.

Glass Industry. Description of plant of Kimble Glass Co. at Vineland, N. J. Plant noteworthy for 3 reasons: Development of manufacture of glass by automatic machinery; manufacture of precision scientific glass ware in U. S. on commercial scale, and for training of force of skilled glass workers capable of blowing and working up most complicated articles. *G. L. MONTGOMERY, Chem. Met. Eng.*, 4-26-22, 2500 w. CJW.

Silica Occurs in Many Forms. Occurs principally as opal, flint, diatomaceous earth, tripoli, etc. Gives other forms and various uses. *RAYMOND B. LADOO, Cement, Mill & Quarry*, 4-20-22, 1800 w. CS.

Non-Metallic Mineral-Filler Industry of South. Covers mica, talc, whiting, ocher, silica and slate flour. Gives their location, characteristics and uses. *W. M. WEIGEL, Cement, Mill & Quarry*, 4-20-22, 2500 w. CS.

Expansion and Contraction of Concrete Due to Moisture. Gives results of experiments at University of Illinois and methods used. *Concrete Products*, 4-22, 1500 w. CS.

LUMBER-WOOD PRODUCTS

Railroad Buying Will Affect Lumber Market

FROM a careful survey of conditions, new business, ideas of Eastern buyers, and future demands, it is evident that the second quarter of the year will witness a greatly increased demand for lumber. For the past week, new business from all sources in the West Coast territory exceeded production by seventeen percent. And inasmuch as foreign lumber buying is at a standstill there, it is clear that the increase is in the American consuming markets. The mills for the week booked 2005 carloads, 30,000 feet to the car, an increase over the previous week of sixty carloads. This is an average for the two weeks of 300 to 400 carloads more than that of the past six months. As a result, the mills are contemplating a general advance in prices, and wholesalers

are cautioning each other against selling short for delivery in future on today's quotations. The impression is that they will be unable to buy at the mills and so take heavy losses.

According to figures published in *The American Contractor*, the mills cut 75,778,037 feet, shipped 85,370,704 feet, and sold 88,836,484 feet during the past week. Of the new placements, thirty-one percent, or 19,668,696 feet, is for the Atlantic consuming trade. Production by 134 representative mills is now only ten percent below normal. It is reported that the railways, facing an emergency for new ties and maintenance materials, are about to begin placing orders. And it is pointed out that the weight of this business alone will force the market upward.

Sizes and Grades of Pacific Coast Woods. Various grades of West Coast lumber may be gathered into two general groups: "Uppers," which refer to all grades, No. 3 clear and higher, and "common," which covers all grades lower than No. 3 clear. Upper grades are taken from outer portion of log and percentage of clear lumber obtainable generally varies directly with diameter of log. Thickness of clear stock obtainable varies in same proportion. Two general groups of Pacific Coast lumber, upper and common, are each subdivided into three classes: Stock items, accumulative items and special stock. Stock items, those which are unavoidably produced through manufacture of some stock or special item. Special stock is that manufactured to order for some particular purpose. Orders for stock items are usually acceptable and under normal conditions can be shipped promptly; orders for accumulative items should always be sold subject to stock on hand, and should never be accepted without authority from the shipper and priced on his special quotation. As general rule, all common grades of West Coast lumber and all upper grades thicker than two inches are shipped green, and all upper grades two inches and less in thickness are kiln dried. *Timberman*, 4-22, 2500 w. HHH.

rule of little help in measurement of standing timber. Volume tables used by foresters to facilitate accurate estimate of standing timber give contents of trees of standard sizes. Estimates should be conservative, rather than too high. Cost of estimating should not exceed 1% of value of stumpage. *AUSTIN F. HAWES, Wood Turning*, 4-22, 2000 w. HHH.

Extracting Turpentine from Sawn Lumber. Two processes employed: dry kiln and pitch extraction. Dry kiln process not materially different from ordinary drying practice, main difference being that during first 24 hrs. drying is done by steam instead of by air. Steam bath dries lumber better, with less checking and warping. In pitch extraction process, only lumber having large amount of pitch is treated. When the process is used, green chain grader marks "fat" pieces, which are then stacked on trucks and run into special retort or kiln, which has steam coil in bottom. After door is closed, definite amount of turpentine is pumped into retort and is boiled by steam in coils, which extracts pitch from lumber. *W. H. MASON, Lumber Trade Jour.*, 4-1-22, 1400 w. HHH.

Forest Conservation. Elimination of waste in various materials used makes for efficient means of forest conservation. Rapid deterioration of shingles results from wire nails, cutting shingles too thin, improper painting. Other sources of waste: failure to preserve railroad ties, extravagant use of newsprint paper, unpainted frame buildings, careless lumbering. *ALBERT V. S. PULLING, Amer. Forestry*, 4-22, 2000 w. HHH.

Forestry Investments. Practice of forestry does not appeal to individual investor for reason that it requires too long a time to realize profit. Taxes paid by individual also a drawback. Extensive supply of timber needed for future demands to be secured only if state and federal government engage in practice of forestry. *JOHN L. KAUL, Lumber Trade Jour.*, 4-1-22, 400 w. HHH.

Uniform Grades of Lumber. Grading of lumber not an exact science, but defects admissible to any grade should be classified and quantity of defects permissible clearly stated in specifications to avoid disagreement when lumber is shipped. *J. W. MARTIN, Lumber Trade Jour.*, 4-2-22, 1000 w. HHH.

Need of Lumber Standardization. Last article of series. Gives twenty reasons for standardization. Discusses variations of sizes, and recommends lumber measured by fractions for thickness, same as iron and steel. Should be uniformity of nomenclature. About 1000 different species of trees native to United States. Of 35 to 40 species of pine alone are known by 300 common names. *DAVID G. WHITE, Amer. Builder*, 4-22, 1600 w. CS.

Estimating Timber Stands. In developing logging operations for large forest area method of transportation one of most essential elements to success. Imperative to decide in beginning what kind of road, railroad or flume system is most economical. Cannot be determined without accurate estimate of amount of lumber to be hauled. Log

More Mines Being Operated

THAT business throughout the mining West is improving, is indicated by the news which comes through the newspapers of the mining districts from Montana to Mexico; from reports gathered from the mining machinery concerns of Salt Lake City, and from mining supply houses and agencies generally.

According to the *Mining Review*, many orders and esti-

mates given and received during the last several months are now being resurrected and given attention.

Unfavorable weather conditions in most of the mountain camps has been responsible for delay in shipping goods that had been ordered, but it is expected that within the next thirty days the roads will be open and that operations will be resumed at a great many properties.

Asbestos Mining and Milling. Discussion of occurrence of asbestos. Chrysotile occurs in two geologic associations: cross-fiber veins are associated with serpentine in limestone or dolomite and in serpentine derived from peridotite or pyroxenite. Geological features described in detail. Understanding of this local geology an essential aid to proper working of deposits. Three methods used for mining: open pits, "glory holes" and shrinkage stopes, combined open and underground workings. Object of mining to recover largest possible amount of crude asbestos. "Crude No. 1" means all hand-combed veins of unbroken fiber length of 1 in. or over. This is sold on color and length, Thetford product being extremely silky, white and of great tensile strength. No. 2 crude averages $\frac{3}{8}$ in. and refers to material recovered from veins between $\frac{1}{2}$ and 1 in. long. "Run-of-mine" crude refers to product in which lengths have not been carefully sorted. To be concluded. W. A. RUCKEYER, *Eng. Min. J.-Press*, 4-15-22, 4500 w. CJW.

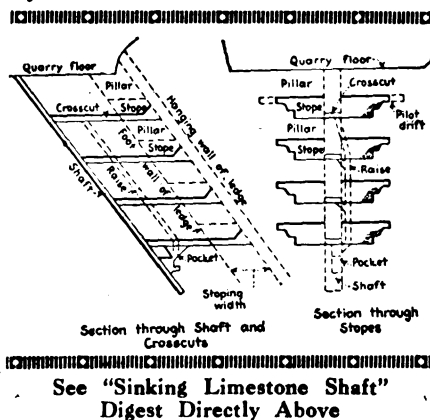

Lining Mining Shaft. Concrete was used for lining and wood for stairways. Concrete was machine mixed on surface, lowered into the shaft, where work was started 120 ft. from surface (first 60 ft. were timbered). Lining was carried up to section that was lined with wood and then stopped. Concreting was then started at 180 ft. below surface and work continued in 60-ft. sections, one section being finished, working upward and then another 60-ft. section started. Much time was saved by this procedure. It facilitated building of stairway and pouring of concrete lining. Also avoided temporary timbering throughout entire length of shaft. A. F. BROSKY, *Coal Age*, 4-6-22, 2000 w. CJW.

Fan-Pipes in Metal Mines. Two most important things that need attention in small fan-and-tubing installations are control of leakage and of temperature. Present losses on lines of 1500 to 2500 ft. may be close to 90 per cent. Information needed on best type of joints and range of leakage loss for more commonly used galvanized-iron pipe joints; same for canvas tubing, method of preventing decay of canvas tubing, amount of heat produced, use of water sprays to reduce temperature, use of exhaust methods and booster fans, etc. D. HARRINGTON and G. E. McELROY, *Arizona Mining J.*, 4-15-22, 1500 w. CJW.

Diamond Drilling. Description of operations in exploring Red Ledge area of Seven Devils mountains. Ore varies in texture from extremely soft silver-copper sulfide to hard disseminated chalcopyrites. Most of holes drilled with 1 11/16-in. bits, which were set with 14 stones, 6 on inside and 8 on outside, 2 of which were small stones, to act as reamers. Sampling was done by using a Longyear core-splitter, one-half being left for classification and future reference. Results show that preliminary exploration can best—depending, of course, on nature of rock and ore bodies—be done by diamond drilling. F. A. KENNEDY, *Eng. Min. J.-Press*, 4-1-22, 1200 w. CJW.

Mineral Belts. General discussion of conditions in and about Great Basin province, urging the need of exploration. Old prospecting methods are obsolete and useless. 95 per cent of mineral outcrops in U. S. discovered. Average life of mine about 11 years. Since production must double every 10 years to supply constantly growing demands, shortage of new mines would appear to be in sight. Place of economic geologist in this work pointed out. S. F. HUNT, *Salt Lake Mining Rev.*, 4-15-22, 2500 w. CJW.

Sinking Limestone Shaft. Underground method is being used by American Lime and Stone Co., of Tyrone, Pa., to procure high-grade limestone. Shaft was sunk in limestone in floor of quarry about 80 feet from foot wall of the "good stone" ledge. It is 8 x 24, has 4 compartments, provision being made for 2 skipways, 1 cageway, and 1 ladder and is 391 feet deep on inclination. Section through stopes (cut) indicates proposed method of mining. J. H. STOVEL, *Eng. Min. J.-Press*, 4-8-22, 1000 w. CJW.

See "Sinking Limestone Shaft"
Digest Directly Above

Anthracite Mine Fire. Description of conflagration of unknown origin in Hollenback Colliery, Wilkes-Barre, which, 10 minutes after discovery, had so great headway that current of air in main hoisting shaft was reversed and sheet of flame ascended to surface and rose above shaft opening to height of 75 feet. Two hours after fire was discovered, city fire department had it under control. Water was poured down shaft for number of days to make sure fire was extinguished. Coal which caught on fire was fought by direct attack. D. C. ASHMEAD, *Coal Age*, 4-13-22, 1500 w. CJW.

Mexican Mining Law. Title to all mines is in Republic. Pertenencia is claim unit and consists of 100 meter square of surface. Any person may locate piece of mineral ground containing as many pertenencias as he desires. Extralateral rights not recognized. Foreigners may not acquire direct ownership of lands and waters which are not distant at least 62.5 miles from national boundary line or 31 1/4 miles from coast line. Method of procuring title explained. D. A. RICHARDSON, *Eng. Min. J.-Press*, 4-1-22, 2500 w. CJW.

Instruction in Mining Methods. Description of mining courses at Haileybury high school, Ontario. Two objects are: Means of giving boys desirous of following mining practical and technical foundation upon which to start life work; preparatory course for those wishing to enter Queen's School of Mines. Location ideal, since it is near silver mines and growing gold districts and in midst of diversity of geological formations. Plant facilities described. *Canadian Machinery*, 4-13-22, 1600 w. CJW.

Asbestos. Modern underground mining methods now being introduced in Quebec fields. More than fifty classifications of mill product. In testing 3 screens used: top, No. 11 wire, 2 mesh; center, No. 17 wire, 4 mesh, and bottom, No. 18 wire, 10 mesh. 16-oz. fiber used and screens run for 2 min. Fiber retained on each screen weighed separately and total must be 16 oz. Simple crushing, screening and suction used to separate and grade asbestos. Expense per ton of fiber (mine) is \$147 at Black Lake, and value of product averages \$330. Approximate cost of 800-ton per day plant given as \$326,000. W. A. RUCKEYER, *Eng.-Min. J.-Press*, 4-22-22, 5000 w. CJW.

This Map Equipment will help You Increase Your Sales

Many of the largest and best-known business organizations in the country—such concerns as Quaker Oats, Pillsbury, Studebaker, Armour, Sherwin-Williams, Diamond Match, U. S. Rubber, etc., etc.—use the Multi-Unit System of washable business maps to visualize their sales and distribution facts and to give them a graphic picture of their sales organization at work.

This map equipment will enable you—as it enables these firms—to tell at a glance what your distributors, dealers and salesmen are doing—to plan your advertising and selling campaigns with all the facts about your territory before you, and to check up on results from day to day. These facts are shown by marking on the maps with ink, crayons or water colors—erasing and changing the marking as necessary—and by using colored tacks.

In this manner you can outline territories, indicate salesmen's routes, show the location of distributors, dealers, branches, agents, etc., spot the good and bad towns

and mark down sales quotas, sales totals, comparative standings, and other important data.

You can use one or more of the wing surfaces for mounting graphic charts showing sales and production data, or have them finished with our special blackboard surface, as illustrated above. On this black board you can chart the records of the salesmen, distributors, dealers, etc., and keep a comprehensive summary of all sales and distribution facts.

The facts shown on your maps can easily be kept up to date with your business—a girl can do it in a few minutes each day. The maps are large-scale, clearly engraved and completely indexed—prepared primarily for business use but equally valuable for general reference work.

There is a Multi-Unit System of washable maps that will meet your requirements, no matter how large or small your territory or business may be. The cost is small—the returns on the investment large.

Would you like to know more about how washable maps would help you? We shall be glad to send you some very interesting facts telling how firms with similar selling problems are using them to splendid effect. In writing, please tell us what territory you cover. Address Dept. I. D., Murphy Bldg., Indianapolis.

PRINTING • PUBLISHING

Publishers to Work for Open Shop

AT the recent convention of the American Newspaper Publishers Association in New York, it was decided, after considerable discussion, to establish an open-shop division. This new department, according to the terms of the resolution, will "in no circumstances" be used merely as a strike-breaking organization." According to *The Fourth Estate* the open-shop division is intended to provide publishers, who wish to put in the open-shop as a matter of principle and not of expediency, with skilled men.

The labor policy of the convention was indicated by President Williams' address at the opening of the meeting: "Many insist that labor costs are too high and that the chief end to be sought is a reduction in the wage scales of skilled

workmen. While it is conceded that some reduction is in order from the very top-notch prices still being paid, and while these reductions seem certain to come in course of time . . . publishers generally are not averse to giving labor a high wage in keeping with the experience and skill required by the business; but in return they have a right to insist upon a day's work in constructive labor, producing something of real value to the employer."

Negotiations between the publishers and the pressmen's, stereotypers' and photo-engravers' unions are reported to have reached a favorable stage, and new agreements with them are expected. But the typographical union has so far made no reply to the latest statement of the publishers' terms.

Wireless Telephone, Printing and Publishing. Present popularity of radio-telephone due to ready backing given by printers, publishers and advertisers of any proposition which seems good. Radio interest not a fad, but here to stay; can be made asset to industries not now receiving benefits from boom. Many prominent magazines, all big metropolitan dailies, carry special radio department or page which draw special advertising. Publishers in small cities should join in. Already more than 80 broadcasting stations. Radio receiving sets range from \$10 to several thousand; popular sets from \$30 to \$70 have 50-mile wave length, approximately. Printer or publisher within this radius of broadcasting station has wonderful opportunity adding department of popular interest, and working up new business. Department should present programs of at least all stations within radius, have question and answer section, definitions of technical terms, classified exchange column. Draws advertising from manufacturers throughout country. EARL H. EMMONS, *Amer. Printer*, 4-5-22, 1700 w. MBB.

Newspaper Alone Held Responsible. Colorado Supreme Court renders over-

ruling decision in libel suit of Ellen Switzer against Caroline M. Anthony and Denver Express Publishing Company. Complaint alleged defendants conspired publish supposed statement of hers defaming the flag. Court directed verdicts for defendants. Overruling opinions were: (1) no conspiracy shown as alleged, (2) name in article spelt Switcher, (3) no malice, nor want of good faith shown, Mrs. Anthon discharged, judgment as to the Denver Company reversed and remanded. *Editor and Publisher*, 4-15-22, 1500 w. MBB.

Publisher's Responsibility to Advertisers. During past two years, efforts of publishers of industrial journals have been concerned with helping manufacturers produce goods most economically. Lately this has grown to aiding in planning and carrying out merchandising and advertising policies. Such responsibility cannot be shirked. Today, as never before, advertising is on trial in court of public opinion. All interested should see advertising pays advertisers 100%. *A. B. P. News*, 4-22, 600 w. MBB.

Special Elevating Equipment. Description of specially designed elevator equip-

ment at Curtis Publishing Co. plant, Philadelphia, to handle heavy rolls of paper from basement to various floors. Automatic and operated by one man. M. W. HIBBARD, *Eng. News-Record*, 4-6-22, 800 w. CS.

A Frank Word from Engravers. American Photo-Engravers' Association in a comparison between the years 1915 and 1921, only period in which possible to find standard of comparison, state reason for increased price of photo-engravings cannot be answered in one sum or in one term of percentage, because increase varies according to size of plate. Comparison to be accurate must be made on definite number of plates of definite sizes. Statistics show price increase during war was based on actual cost of production. *Ben Franklin Monthly*, 4-22, 1000w. MBB.

Canadian Press Plans Broadcasting Ban. Amendment has been proposed prohibiting broadcasting of news by newspaper members of the Canadian Press, due to feeling against profit to individuals from use of news belonging to all. This amendment is in line with recent general order promulgated by Associated Press headquarters here. Second proposed amendment would divide entire expense and distribution of news into two classifications: national cost and circuit cost. *Editor and Publisher*, 4-15-22, 800 w. MBB.

Get Timelines into National Copy. Retail advertising is always timely; framed with view to current events, progress of seasons and customary occasions of merchandising year. This gives immediate news value and sales appeal. Value of timeliness seldom utilized by national advertisements to fullest extent; could profitably study methods of retailers. FRANK H. WILLIAMS, *Editor and Publisher*, 4-8-22, 1500 w. MBB.

So You're a Journalism School Graduate! Newspapers recognizing advantages afforded in schools of journalism depend on them for new staff material, getting pick of students who have mastered thorough training, rather than repertoire of new tricks. Close cooperation between schools and newspapers proved mutual benefit. L. N. FLINT, *Editor and Publisher*, 4-8-22, 2000 w. MBB.

The Fuss Is All About a Two-Cent Stamp

The point of this picture is the electric stamping machine in combination with a cash register device. The machine seals and stamps 25,000 letters an hour, at the same time keeping a record of how much postage money is due Uncle Sam, and saves the labor of four clerks.

They Practice What They Preach

The Bassick Manufacturing Company, Chicago, makers of the Alemite Lubricating System, believe in efficient bearing lubrication and in straight-line hauling. They keep materials off the floor, save labor-wasting repilings, and speed the movement of parts in process by trucking the Stuebing way.

Production Manager J. Henly Frier says: "For the past two years we have used Stuebing Lift Trucks exclusively in our factory, and count them indispensable. Our average load is 2500 pounds and consists chiefly of steel

stampings and brass fittings. To date our Stuebing Lift Trucks have not cost us one penny for repairs. We recommend them to every plant whose interior hauling costs are higher than they should be."

Other progressive industries like Ford Motor, Westinghouse Electric, Procter & Gamble, Bush Terminal, and Cincinnati Milling Machine, are using Stuebing Lift Truck Systems to cut down trucking expenses and to reduce overhead. Let us show you what a Stuebing System will save in *your* plant.

One man rolls a Stuebing Lift Truck under a loaded platform, lifts it with an easy pull on the steering lever, quickly moves it to any location, and safely lowers it to the floor.

The Stuebing Truck Company, Court and Broadway, Cincinnati, Ohio

LIFT TRUCK SYSTEMS

RUBBER • PLASTICS

Higher Rubber Prices Expected

A MINIMUM price of thirty-six cents per pound for crude rubber supplies in 1927 is predicted by *The India Rubber World*. It is believed that political disturbances in the East or increased export taxes may result in much higher price levels. The figures in the accompanying tabulation are based on an exhaustive examination of rubber producing conditions

planted and still "in hand" December 31, 1920, and since this date new planting has been negligible. It is not expected that a material increase will occur before 1927.

In the item of shipping and selling expense a profit of two per cent to the importer is included, without which, it is asserted, his service to the industry would have to be suspended.

Potential Plantation Rubber Production and Costs in 1927

Assumptions: (1) Normal or par exchange for sterling, guilders and Straits dollars; (2) Total acres in full tapping 3,000,000, of which 450,000 will be small so-called native or Chinese estates producing only 50 per cent first quality rubber; (3) Labor: Same wages as at present. This will probably be increased if full production is to be made with labor reengaged in India or Java; (4) Shipping and selling expenses (without interest charges or export tax) same as 1922, that is, 2.8 cents American currency per pound.

Producing Acres	Per Cent of Total	Lbs. Per Acre First Grades	Total Lbs. First Grades	F. O. B. Costs First Grades, Cents	Delivered Cost First Grades, Cents	Lbs. Per Acre Off Grades	Total Lbs. Off Grades	F. O. B. Costs Off Grades, Cents	Delivered Cost Off Grades, Cents	Lbs. Per Acre All Grades	Total Lbs. All Grades	Delivered Cost All Grades, Cents
450,000	15	375	168,750,000	16	18.8	75	33,750,000	18	20.8	450	202,500,000	19.13
1,050,000	35	325	341,250,000	18	20.8	75	78,750,000	20	22.8	400	420,000,000	21.17
1,050,000	35	275	288,750,000	20	22.8	75	78,750,000	22	24.8	350	367,500,000	23.23
450,000	15	120	54,000,000	24	26.8	120	34,000,000	24	26.8	240	108,000,000	26.80
3,000,000		284.25	852,750,000			81.75	245,250,000 = 22.3% of total			366	1,098,000,000 = 490,000 long tons	22.43*

throughout the world over a period of several years. No accurate data are available on the subject of total acreage and there is legitimate justification for difference of opinion as to the area of so-called "native" states of less than one hundred acres. The round figure employed probably exceeds the total acreage

The average cost estimated for 1927 could not be realized today under full tapping conditions because of high costs and low production on areas that are still immature. Without reckless bark expenditure the average yield per acre in 1922 would not exceed 330 pounds.

Solubility of Sulfur in Rubber. This property is of practical interest since it is one of two determining factors in well-known phenomenon of blooming. Presence of excess of free sulfur unquestionably plays an important role in aging of rubber goods. Further, number of theories as to mechanism of vulcanization presupposes as first step melting of sulfur and its solution in rubber. Solubility of sulfur in rubber apparently increases slowly with vulcanization coefficient, more rapidly as temperature increases. With coefficient greater than 7% combined sulfur, solubility values could not be obtained by method used because rubber became almost impermeable to free sulfur. Impermeability probably has more to do with non-blooming of rubber stocks than

has slightly increased solubility for free sulfur. C. S. VENABLE and C. D. GREENE, *J. Ind. Eng. Chem.*, 4-22, 1500 w. CJW.

Composition of Tires. Eighty per cent of materials for high-grade pneumatic tires are of vegetable matter and consequently perishable; rapidity of perishableness depends largely on extent of unnecessary exposure of tire to light, heat and moisture, as well as avoiding destructive abuses such as cuts, abrasions and rupture. Careless destruction of rubber tires amounts to more than \$1,000,000,000. Proper care would save over \$100,000,000 of this. Majority of tire failures take form of punctures or blowouts. Blowouts are due to overloading, under-inflating, overspeeding,

faulty wheel alignment, driving in car tracks or ruts, neglected cuts and improper use of anti-skid devices. Discusses each of these abuses. *Automobile Jour.*, 3-22, 2000 w. BS.

Construction and Nomenclature of Many Types of Tires. Points described. Carcass, bead, chafing strip, sides, tread, breaker strip. Straight side tire almost universally used. Rubber and cotton greater part of pneumatic tire. Description of rubber and cotton. Process of machine and hand manufacturing. Standardization of sizes. *Amer. Garage and Auto Dealer*, 4-22, 3000 w. BS.

Asphalt. Fourth of series on origin, manufacture and use. Cover use in ancient times. JOHN K. COSTELLO, *Building Material*, 4-22, 4000 w. CS.

Oil: Russia's Ace

(Continued from page 919)

is too much money invested in the enterprise, but too much is at stake in the way of fuel oil for the British merchant marine and the British fleet. In 1916 7,000,000 tons of oil were exported from Baku alone. If Soviet Russia will recognize, in one form or another, former foreign investments in Russian capital or properties in which foreign capital has been invested, this vast prize in oil is Britain's. It is worth going to Genoa—or even to Canossa—for.

Similarly with the French, who were large investors in the Grosny oil field before the war, and who, since the British coup over the Baku field, have been following the British example in buying oil properties around Grosny from the impoverished owners. There was a time when the French were hoping to secure these fields through an arrangement concluded with the Turks at Angora last October for a new war against Soviet Russia this year. One hundred million francs in gold were to be advanced by France to the Turks for that purpose, in addition to 200,000,000 francs' worth of military supplies. But the time does not appear propitious for a new adventure in counter-revolution, and, instead, there seems to be a tendency on the part of the French, also, to reach an agreement with Soviet Russia, in which oil will unquestionably play a part.

Where We Stand

AND we? What is our part in this game? So far, the best we have been able to secure has been permission from the British for the Standard Oil Co. of New Jersey to develop a small field in Persia. The Dutch have refused to let us go as far as our industry, money and energy will take us in the Dutch East Indian fields. A fence is gradually being built around us to confine our oil assets to our own territory—where we graciously permit foreign capital to come in and exploit our oil resources as it likes. It is evident that, sooner or later, we, too, must turn our attention to the Russian field.

And so, after all, hunger may stalk in the valley of the Volga, and poverty and economic breakdown reign from Archangel to Sebastopol. But so long as the second largest oil field in the world is in Russia, the People's Commissars in Moscow can afford to draw cards to Russia's ace in the hole.—PAXTON HIBBEN, F.R.G.S.

Race for Russian Trade

(Continued from page 920)

There is an opportunity in Russia right now for American business men, and they can take advantage of it if they will without violating any rules of the State Department. Secretary Hughes, on the day when the report of the oil agreement between Russia and the Shell combine came to this country, explained the attitude of the United States Government toward Russian trade. He said:

"There are no legal obstacles to trade

with Russia. The obstacles that exist to trade with Russia are due to the situation in Russia, which is in control of those who dominate the affairs of Russia. . . . We are most desirous to do what we can to aid in Russia's recuperation, but they [the Soviet officials] must establish the basis for such recuperation."

Apparently the Russian officials have been able to establish such a basis to the satisfaction of the British oil interests and the International Harvester Co. and other business organizations. Trade with them would be facilitated if the State Department saw fit to give political recognition to the Russians. But without political recognition it can still exist. Its extent will depend upon American initiative and trading ability.

Milk from Oil Seeds

THE cow will be deposed from its high and mighty position, if a new discovery recently made in Germany turns out the way the inventors claim it will. Oil is extracted from certain seeds, as, for example, the sesame seed, etc. A sort of milk can also be obtained from these seeds, a product which contains the greatest possible portion of the nitrogenous substances that are originally present in the seed itself. The seeds are mixed with quartz and emery and ground up by abrasion with these substances and then the milk is thrown out by means of a centrifugal machine. About a liter of milk can be obtained from 100 grams of seeds. The milk contains 90 per cent water, 3.5 per cent of fat, 2.5 per cent of carbohydrates, 3 per cent of nitrogenous matter and 1 per cent of mineral salts. The cost of the milk is only two-fifths of cow's milk, and by treatment with a certain ferment, its taste can be changed so that it is difficult to tell the artificial product from natural cow's milk. The milk is easily digested and possesses all the characteristic properties of the natural product.

Handling Scrap

A SOLUTION of the scrap problem is put forward by the National Association of Cost Accountants in a recent bulletin which outlines the following course of action: (1) Prevent scrap at the source by study and elimination of causes and by reclamation. (2) Handle scrap efficiently by segregation at the point of origin, systematic collection and transportation and preparation for profitable disposal. (3) Dispose of scrap for the best returns by maximum consumption of scrap within the factory, finding the most profitable markets and meeting the demands of consumers. (4) Account for scrap correctly by getting accurate costs on the loss and salvage value, crediting scrap to material or individual lines of product and maintaining sufficient records for the compilation of reports.

Russian Trade

(Continued from page 923)

steel manufacturers as a whole, approximately \$6,000,000.

Among the products exported from Russia to the United States, the most important articles are: flax, furs, hides and skins, bristles, sugar-beet and grass-seed, sausage casings, carpets and rugs, platinum, manganese ore, etc.

The increase during the years 1914 and 1917, while largely war materials, included also railway supplies and materials, automobiles, leather and manufactures thereof, copper, steel rails, railway cars, wire, and miscellaneous manufactures of iron and steel.

Absence of American Ships

IN the years immediately preceding the war, about half of Russia's foreign trade proceeded by water. In 1913, the comparative tonnage of ships of various nationalities which entered Russian ports was as follows:

	Per Cent
British	26.7
Russian	7.5
German	13.7
Swedish and Norwegian.....	13.6
Danish	6.8
Italian	4.4
French	2.7

During this period, it is interesting to note that the United States were not listed among the nations under whose flags sail the ships that visit the Russian ports. This fact is very significant, as in all present-day discussions concerning the future direct Russian-American trade, the question of marine transportation receives considerable attention, being regarded as one of the primary factors in such a development. Since the war, however, American ships gradually appeared with cargoes of goods in Russian ports. With the recent development of the United States merchant marine, this obstacle to Russian-American trade expansion is removed and opens the route to direct trading.

The Changed Situation

AN analysis of the Russian-American trade statistics shows the extent to which the rôle played by the United States has been shifting and fluctuating—from half billion dollars in 1916-1917 to only several tens of millions in the pre-war and present time. The present foreign trade situation, broadly viewed, suggests that this is a period of readjustment, in which the re juxtaposition of the former relative status of several countries on the international market is taking place.

Almost every revolution, after it has accomplished its definite aim, disorganization, reevaluation and a return to peaceful living, is followed by a period of intensive economic development of that country in which it has taken place. Russia, like the United States after the Civil War, will pass through such a course, and judging by recent events and available data this period has already assumed concrete form in Russia. Past economic development has succeeded barely in scratching the surface of Russia's vast natural resources.

Foreign trade will play the chief rôle in Russia's industrial recovery and economic development. Her imports and

exports will constitute an essential portion of the world's markets. If in 1913 Russian foreign trade reached one and one-half billions of dollars, then in the immediate decade to follow, after her national economy has been put on a sound basis, her foreign trade will rapidly expand far beyond the 1913 figures. What will be the rôle played by the United States?

The answers to these questions are obvious. The rôle of the United States will be proportional to the initiative displayed by American enterprise and the methods and technique adopted for the winning of the Russian market. The United States must adopt the methods and learn the lessons from her successful competitors, particularly those of Germany, when the latter ousted England from the first position on the Russian market.

How Germany Succeeded

MANY causes helped the Germans to maintain the upper-hand over the Russian foreign trade. German manufacturers and exporters established an army of travelers who systematically visited the markets in Russia. Germany sent special expeditions, of a scientific nature, to study the local markets and conditions of trade; formed commercial museums and industrial expositions; resorted to extensive advertising campaigns and distributed on a large scale illustrated price lists, printed in the language of the locality and provided with local weights, measures and prices, and finally paid careful attention to appearance, color and physical condition of goods and adapted them to the tastes, customs and fancies of the people. The Rapallo treaty will, of course, accentuate these advantages.

In other words, the principles and technique of capturing a foreign market have been exhaustively applied by Germany. It is simply what is being done by American manufacturers and exporters to get and keep the South American markets. American manufacturers and distributors are not unfamiliar with the fundamentals necessary to exploit a foreign market. They have, however, neglected their opportunities on the Russian market.

Russia commands a population of about 150,000,000. Her vast urban and rural population is eager for the newer conveniences and comforts that modern scientific and technical development in the whole world has rendered possible. The American Relief Administration and other agencies have done much to acquaint the Russians with American goods. This has tended to make our approach to the Russian people less sensitive and more conducive to success.

Obstacles for U. S.

AMERICAN manufacturers and exporters have a serious drawback which the Europeans have long ago overcome. This drawback manifests itself in the lack of desirable information about Russian industry and trade, especially the present conditions under which Americans could successfully market their products. Up to the present, Americans have made hardly any use of the perfected means and weapons to capture the Russian markets. The old custom of remaining at home and waiting till customers come to them is obsolete and will not make the United

States a factor in Russian trade. The Europeans are utilizing their old fund of information and are clever enough to have realized that, because of the changed political and economic conditions, entirely new data are necessary to be employed at the opportune moment. England and Germany, though weaker financially and less capable to supply Russia's needs than the United States, have recently made remarkable strides and are again competing for the first position.

Americans desiring to participate in Russia's economic revival get their information second and even third-hand from sources inimical to their interests

and too late for the correct start for a profitable venture. Unless more intelligent methods are adopted, Americans will be obliged to work through German, English, or French agencies, scarcely being able to retain their present share of the Russian market.

The Russian situation is approaching a commercial crisis. The Genoa Conference, though the final outcome is yet uncertain, dictates speedy action for Americans. The Germans will exhibit their goods in Russia this summer at an industrial exhibition. Will the United States do likewise? —

V. V. TCHIKOFF and
J. R. MINEVITCH.

WILLIAM TONKS

VICE-PRESIDENT, THE UNION TRUST COMPANY, CLEVELAND, OHIO
PRESIDENT, THE ROBERT MORRIS ASSOCIATES

Relative to complete certified audits, the message of The Robert Morris Associates is to the—

BUSINESS MAN: That honesty welcomes investigation, while reticence creates suspicion and precludes the helpfulness of experience.

BANKER: That you shirk your first responsibility, which is to your depositors and stockholders, when you loan their money without full investigation. You even do the borrower an injustice unless you have sufficient knowledge of his business to prevent or mitigate failure.

CERTIFIED ACCOUNTANT: That you have not earned your fee from the business man unless you have made it possible for him to save or make more money. That you have not earned the confidence of the banker unless your figures, comments and certification present a true and complete picture.

TEXTILES

Will the Wool Industry Move to the South?

IT is believed that a definite turning point has been reached in the wool goods market. After nearly two years of declining prices a decided upward movement has begun. In view of the increased demand reported by retailers and the recent wage adjustments being effected in the clothing industry *Southern Textile Bulletin* believes that wool manufacturers should soon "reach the belated rewards of sane liquidation and pass out of the anomalous position of being caught between a rising wool market and a peak clothing situation, where they and they alone seemed called upon to effect the economies demanded by the consumer."

An interesting development of the improved market conditions is the recent investigation of possibilities for the erection of woollen mills in the South. Since it has been demonstrated in the cotton manufacturing industry that cheap labor, long hours, and natural conditions somewhat favor the

South as a section for profitable production of this class of merchandise, it is believed that the South might also become a wool manufacturing center. In regard to the transportation of raw material, authorities see no reason why wool cannot be delivered to strategic points in the South as cheaply as to New England mills. This applies, of course, only to domestic wool, since Southern ports could be utilized for the receipt of wools from abroad.

It is thought that if the South is developed as a wool manufacturing section the outlook is for increased production and consumption of woollens instead of worsteds, since for some time the trend of demand appears to have been in this direction. While the recuperation of the worsted market may take place in time, many textile experts are of the opinion that woollens will continue to hold a commanding position in this division of the textile industry.

Cotton Manufacturing Production Details. Must group our production details as follows: Details which relate to power and speed; processing of work; mechanical; stock in process; lubrication; humidification; transportation; character of goods; help problems; supervision; conveniences; illumination; temperature; supplies; repairs; tensions; draughts; wages; records; weighings; manipulation; general management. N. O. MARTIN, *Textile Colorist*, 4-22, 4000 w. WRR.

Gummed Cloth Sealing Tape. Puncture test utterly inadequate for determining strength of cloth tape. Tensile strength test not accurate because pressure is not

brought to bear on binding tape in manner in which strain is exerted in making test. Tearing strength test, lengthwise material to be used, properly and adequately determines its strength for binding purposes. This test may be carried out with Elmendorf tester. C. H. CROWELL, *Fibre Containers*, 4-22, 1000 w. CJW.

Use of Lime in Textile Industry. Gives uses of lime in textile industry. Covers: bleaching or "chemicking" process, boiling-out with lime, drying, kier liming. Give number of reasons for renewed interest in lime by textile industry. Cement, Mill & Quarry, 4-20-22, 2000 w. CS.

Fustian Design and Manufacture. This number covers the manufacture of corduroys. Charts. T. WOODHOUSE & A. BRAND, *Cotton*, 4-22, 2200 w. WRR.

OR SALES ORGAN YOU ARE THINKING ABOUT**

Ours is a Planning, Writing, Editing, Printing and Art Service Distinctively Qualified for House Organ Work.

Tell us how much you want to spend and we'll give you a definite idea of the publication that amount will buy. And we will furnish a Magazine or Paper that will fit into your needs.

We Specialize in Industrial and Institutional Publicity Designed to Reach the Employee

Our Service Eliminates Costly Experimentation

Have You Seen the Blue Pencil?

Send 30 cents in postage for a sample copy

The only Trade Paper devoted exclusively to the subject of Employee Publications, House Organs, etc. It deals in a Practical way with every phase of publication work.

Planning, editing, gathering news, articles and information, how to buy and use art and engravings, etc. It contains 80 and sometimes 96 pages of information.

HOUSE ORGAN HEADQUARTERS, 187 Montague Street, Brooklyn, N. Y.

Facts! Facts! Facts!

THINK of the multitude of business facts with which the man of affairs must be familiar.

Facts—thousands and thousands of them—flow by him daily; all flowing together down the stream of our daily, weekly and monthly journalism; a gigantic log-jam of events.

And out of all that mass of complexity, unmarked, hidden from sight, lurk the few facts—the very few—that are really significant; the few that are the key-logs which would release the mass. Who has time to find them, or the skill to pry them loose?

This is the Reason for the Industrial Digest

In each of the 30 important branches of industry and commerce The Industrial Digest employs a man who makes it his business to keep accurately and thoroughly informed regarding all developments of importance. Every two weeks he prepares a careful report; and at a meeting these 30 reports are carefully compared, the individual items are evaluated and a master report is prepared.

A Master Report on Business

This master report is, therefore, a comprehensive survey of American finance, commerce and industry. It makes up, in fact, this issue of The Industrial Digest which you hold in your hands.

The expense of preparing The Industrial Digest is tens of thousands of dollars a year, but since the cost is divided over thousands of business executives, the service is offered to you at the cost of \$5 per year.

In view of the fact that the same service could not be rendered by a department of your own at less than a prohibitive cost, this sum is indeed ridiculously small. It is in no sense a measure of the value of the service to you.

THE INDUSTRIAL DIGEST,
25 West 45th St.,
New York City.

Please send your fortnightly survey of American industry and commerce to me for one year. I enclose five dollars, check or money order.

A Promising Channel for Increased Business

IN order to reduce the capital invested in merchandise and to avoid overstocking, it is believed that the mercantile industries of the country will permanently adopt the practice of making "quick turnovers," carrying small stocks on hand and depending upon fast transportation to replenish them. In these days of rapidly changing styles in women's clothing, there is selling value in the expressions "Just arrived from New York," and "overnight from Fifth Avenue by Express." And although the practice of frequent replenishment of stock by the retailer would make it neces-

sary for the wholesaler to carry a large stock, it is thought that the adoption of such a plan would result in reducing the risks he usually takes in extending credit to his trade. It has been proved in some cases.

The Express Gazette Journal believes that the express business is now in a strategic position, and that the substantial traffic turned over to it by the cloak and suit, women's apparel and boot and shoe trades indicates that the retailers like the present system, and that the wholesalers are quite willing to deal with them on that basis.

Prevention of Freight Loss and Damage.

1920 loss and damage bill U. S. and Canada nearly \$120,000,000. Robberies 20% of claims. Next item unlocated damage. Much caused by rough handling of cars. Cars should not be coupled at speed higher than 2 miles per hour. Next item defective or unfit equipment and wrecks. Train should be encouraged to exchange experiences. Many subjects suggested. Claim prevention calls for education and co-operation. Safety and Claims work overlap. Car Department can do much keeping cars fit and classified as to freight they may carry. Purchase and Storage Department can help when buying new equipment. All railroad men should work together. *Railway and Locomotive Eng.*, 3-22, 1600 w. CHH.

A Pump-Power Railroad. Between Andernach, on the Rhine, to the top of the Khrenenberg, 120 meters above city. Road 550 meters long. Steepest grade 1:3. Two cars, 7 tons each, 8½x2 meters, connected by 1½ in. woven wire steel cable. Ten-ft. sheave at top. One car at top when other at city station. Cars have 6½ cu. m. tank under rear platform and gauge glass. Water taken by car at top, amount depending on number of passengers in other. Telephone communication. Water emptied automatically at city station. 3½ cu. m. need to pull empty car up. Road 1 m.

gauge, single track, with turn out in middle. Middle cog rail, for brake resistance, laid in short lengths (2½ m.) for easy repairs. Guide pulleys each side for cable. Double flanged wheels on outer sides of cars, plain on inside. Each car always uses own side of turnout. Special braking devices. Large tank at top 36 ft. diam. x 8 ft. deep, piped to Summit station. Very little power used, week days 2 to 3 hours total pump time, 6 to 8 hours Sundays and holidays. Only water for cooling brakes and for evaporation make up taken from city mains. Guards on cars run motor and pumps; operating expense is a minimum. *ANDREW GOOBECK, Scientific American*, 4-22, 1500 w. CHH.

Cooperation in Road Building. Discusses how all forces promoting highway construction can unite their efforts. Gives ten interests involved in cooperation: People as whole, legislators, engineers, contractors, manufacturers of materials, manufacturers of tools, railroads, bankers, bonding companies, labor. Also mentions trade press. *WM. ORD, Highway Engr. & Contractor*, 4-22, 1500 w. CS.

Railway Curves: Superelevation and Maintenance (I).

Pre-war estimate operating cost increased \$1 per degree curvature per daily train per year, and each 12° adds 1% to labor cost of maintenance. Greater wear and displacement of rails, fastenings, ties and ballast. Superelevation of rail compromise between requirements for fast and slow trains. Based largely on rule of thumb. Formulae modified by local conditions. Speed a governing factor. No thorough recent study. Rules and tables of different roads show wide variations in amount of superelevation and in treating runout on spirals or tangents. *E. E. R. TRATMAN, Eng. News-Record*, 3-16-22, 3200 w. CHH.

Locomotive Boiler Welding—Expert Report.

For Master Boilermakers' Association Convention, May 23-26. Good welding depends mainly on skill of operator. Electrodes should have approved chemical contents to give tensile strength; for fireboxes, good flowing qualities. Operator for fireboxes should weld specimen once a month, to be tested for tensile strength. Must get at least 75% of steel strength. Work must be prepared, cleaned and bevelled. Seams well fitted, bevelled 45°, ¼ in. to 3/16 in. space at bottom of V. Detailed instructions for welding complete fireboxes, making knuckle patch, preparing half side and door sheet, patching around staybolts, in flue sheets, etc. *Railway and Locomotive Eng.*, 3-22, 2300 w. CHH.

Milling Eccentric Keyways in Locomotive Axles in Wheels.

Device has U-shaped cast steel saddle chained and clamped to axle. Dovetailed slot in top takes tool slide. Tool driven by air motor or flexible shaft. Tool is end and side milling cutter of usual type, with vertical and horizontal feed. Is set and fed down to depth of cut and then fed horizontally. Ball bearing for vertical thrust and special locknut to hold it. Six-inch travel endwise. *Railway and Locomotive Eng.*, 3-22, 1400 w. CHH.

Unique Concrete Track Construction.

Gives description of reconstruction of British Columbia Electric Railway tracks with special concrete headed to eliminate ruts and provide proper flange-way. *E. N. HORSEY, Electric Traction*, 3-22, 1300 w. CS.

(From United States Investor)

FRICITION IN BRAINS

Machine friction increases your wear, upkeep charges, power losses, and decreases your available power, production, and profits. But machine friction loss is a drop in the bucket compared to the mental friction loss in the minds of your employees which cuts down their interest, energy, and productive effort. You yourself couldn't do your best work if your mental attitude was one of misunderstanding, fear, and cross-purposes. Why expect it of your employees? Most manufacturers aim to reduce machine friction through adequate lubrication, but few think of piling up the mental machinery in the plant. Would you excuse your engineer if he oiled half of *his* machinery?

U. S. Factories in Canada

(Continued from page 925)

throughout the country are anxious to have prospective manufacturers appraise the advantages of their own particular towns and extend every co-operation and assistance in locating. The railways of Canada maintain special industrial departments for helping manufacturers who wish to locate along their lines. Their staffs have a wealth of information on hand covering locations of natural deposits, available industrial sites, suitability and advantage of locality, and their experts give advice on settlements, having at their finger ends knowledge of all pertinent factors.

Canada has undergone a trade revolution since the termination of the war and the Canadian manufacturer has become instilled with a new ambition and vision. The inevitable outcome is the greater ability the Canadian manufacturer is exerting every effort to supply all the needs of the domestic market to the exclusion of the foreign, which means mainly the United States, since Canada does by far the greater part of her purchasing across the line.

Therefore, the United States manufacturer must go to Canada if he is to hold his own in the Canadian market.—
EARLE W. GAGE.

Tax Exempt Bonds

(Continued from page 926)

tice saves the Government the expense of collecting a tax yet does not reduce its revenue. If the bonds were taxable they would bear a higher interest rate, and the Government would have to pay out in interest what it would collect in taxes. Thus, it is argued, to make a bond tax-free entails no loss to the Government.

The opponents of tax exemption do not deny the weight of these arguments from the Government's standpoint, but they venture to question whether it is wise for a Government to give itself such advantages over the industrial borrowers on whose success the prosperity of the country largely depends.

Tax Exemption Never Tested

STATE and local obligations are left tax-exempt for theoretical, not practical reasons. It is believed that the Federal constitution forbids Congress to tax them. This matter has never been the subject of a conclusive ruling by the United States Supreme Court since the passage of the Sixteenth Amendment to the Federal constitution, which gives Congress the right to "lay and collect taxes on income from whatever source derived."

Constitutional lawyers hold that this amendment does not authorize the taxation of State, municipal and county bonds because "the power to tax is the power to destroy," and the constitution does not contemplate that the Federal Government should have destructive powers against the local governments. This principle was established by unmistakable Supreme Court rulings in a number of cases before the passage of the income tax amendment, but since that time the question has not been put squarely up to the court. Congress has accepted the opinion of eminent constitutional lawyers that the words "from whatever source derived," in spite of their apparent sweeping meaning, does not authorize the taxation of incomes derived from State or municipal bonds.

Experts on taxation, among them Professor George E. Putnam of Washington University, think otherwise. They believe that there is a chance that the Supreme Court will uphold an attempt to tax State and local bonds. They urge that an opportunity be given to the court to make such a decision, because, in the words of Professor Putnam:

"The special exemption of Government and quasi-government bonds from the income tax is completely out of harmony with modern methods of just and equitable taxation."

Professor Putnam means, of course, that it is not fair to leave open a way for men of large income to escape taxation. However just this objection may be, it is not the ground upon which business men protest against tax exemption. Their point is that the existence of a large body of tax-free bonds makes it harder for legitimate industry to get the capital it needs. Under present conditions large investors are tempted to keep away from industrial propositions. They can do better by purchasing tax-free bonds. This, it is contended, is a situation unfavorable to business, and one which Congress should attempt to remedy.

For Better Railroad Service

(Continued from page 929)

more so because of the substantial decrease in ocean rates;

Second, to keep prices on farm products in the large surplus producing States at figures lower than are justified by the investment in land and equipment and cost of production;

Third, prolong the period of dissatisfaction among farmers and encourage advocates of economic fallacies of all sorts;

Fourth, improve the position of Eastern truck and fruit growers but add considerably to the cost of milk and dairy products because of the advanced prices of hay and coarse grains necessarily shipped from the West;

Fifth, gradually shift industrial enterprises westward, nearer the surplus food-producing territory;

Sixth, promote sectional rather than national spirit and make more and more difficult large national policies with respect to international affairs.

The most hopeful sign at the present time," Secretary Wallace said in conclusion, "is the apparent recognition of the railroad management that our present high rates cannot be continued without disaster to the railroads themselves and that rates must come down to a point not far, if any, above the pre-war levels."

When to Advertise

(Continued from page 927)

steadily (the index fell from 4.80 to 2.50 in five months) advertising did not go as low as its 1919 summer figures. In the fall, in spite of the continued decline in trade, advertising picked up actively. The volume of space used in October was larger than that of any other month in the four-year period except April and May of the same year.

After October, however, advertising began to slump. November and December fell below the 1919 figures for the same month, and during 1921 as a whole the figures were low. During that year, however, a seasonal increase in the use of advertising space occurred in the spring, when business was still rapidly declining.

Everyone can draw his own conclusions from these figures. The fact that advertising was slower to decline than general business may mean that business men did not realize what was happening until some time after the slump was in progress, or it may indicate that space buyers continued to use publicity as long as their purses could stand it, stopping only when restricted funds made further extensive advertising impossible.

Bank Purchases Affect Bond Market

BUYING by the banks has been an important factor in the rising bond market. Financial institutions hold enormous quantities of investment securities today. It is not to be expected that they will suddenly start to sell, but surely they will not continue buying forever, and when they stop, the market will feel it. For all these reasons I think that bonds are not going a great deal higher for a while."

If this view is sound it means, of course, that now is a good time to float bond issues. Corporations which have been holding off new financing in hope of a higher market are now being advised in several quarters to bring their bonds out now.

Books for the Executive

The following are a few suggestions in the way of books which executives in the several divisions will find useful. But these are only a very few among the large number available. We shall be glad to answer inquiries concerning your needs and supply the books you want, at short notice. Write to our Book Department

Glass, Pottery and Jewelry

ELEMENTS OF GLASS AND GLASSMAKING, By B. F. Biser.

A treatise for the practical glass-maker, giving recipes and formulas for the manufacture of plain and colored glass. 140 pp. \$3.

THE POTTER'S CRAFT, By C. F. Binns.

The whole range of ceramic science is put at the disposal of practical workers in the studio in this book. 171 pp. \$2.

Hardware and Paints

PAINT TECHNOLOGY AND TESTS, By H. A. Gardner.

Valuable for its information on raw products, oils and thinners, the results of elaborate exposure tests and research work. 256 pp. \$4.

HOUSE PAINTING, GLAZING, PAPER HANGING AND WHITEWASHING, By A. H. Sabin.

This book gives the householder sound and safe practice in the manufacture and use of paints and varnishes. 143 pp. \$1.25.

Iron and Steel

PRINCIPLES OF IRON FOUNDED, By Richard Moldenke.

A book that has very definitely been a help to foundrymen in solving their problems. 517 pp. \$5.

COMPOSITION AND HEAT TREATMENT OF STEEL, By E. F. Lake.

A comprehensive book which carefully analyzes of those qualities required for greater strength, resistance to stresses and strains, etc. 252 pp. \$3.

AUTOGENOUS WELDING AND CUTTING, By Theodore Kautny.

A pocket book for the works engineer, welder and student. Authoritative translation of a widely known German work. 157 pp. \$1.25.

Leather

MODERN AMERICAN TANNING, By well-known tannery foremen, superintendents and chemists.

Volume 1 deals with such topics as Hides and Skins, Location and Construction of Tanneries, Rough, Welting and Card Leathers, Upholstery Leather, Sheepskins, Tannery Labor, etc. 292 pp. \$5. Volume 2 contains articles on Tannery Equipment and Management, Leather Tanning, Chrome Tanning, Upper Leather and Glazed Kid, Splitting Leather and Splitting Machinery, etc. 570 pp. \$5.

MANUFACTURE OF LEATHER.

A comprehensive treatise on the subject, from an historical summary to the analysis of leather. 441 pp. \$6.

Lumber and Wood Products

SEASONING OF WOOD, By Joseph B. Wagner.

A treatise on the natural and artificial processes employed in the preparation of lumber for manufacture, with detailed explanations of its uses, characteristics and properties. 287 pp. \$4.

UTILIZATION OF WOOD WASTE, By Ernst Hubbard.

Treats of sawdust as fuel, distillation of wood for recovery of volatile products, manufacture of alcohol and sugar from sawdust, use of sawdust in manufacture of briquettes, explosives and gunpowder, etc. 248 pp., 51 illus. \$4.50.

Machinery

LIBRARY FOR MACHINISTS.

Six books on shop practice written by widely known authorities: Tuning and Boring; Planing and Milling; Advanced Grinding Practice; Automatic Screw Machines; Modern Drilling Practice; Electric Welding. Fully illustrated, total 1800 pp. \$14.

MACHINERY'S HANDBOOK.

For the Machine Designer, Foreman, Draftsman and Toolmaker; a comprehensive collection of data in this single volume. 426 pp. \$4.

MACHINE SHOP CATECHISM.

The editorial staff of the *American Machinist* has compiled this work from answers to over 1000 practical questions which have appeared in that journal. 221 pp. \$2.

AMERICAN MACHINIST GRINDING BOOK, By Colvin and Stanley.

A reference book giving full data on machines, wheels and methods. Of especial interest to purchasers of grinders, to operators and those responsible for results in the grinding department. 383 pp. \$4.

Metals and Metal Products

METALLURGICAL CALCULATIONS, By J. W. Richards.

Three volumes covering the basic principles of chemical calculations and their application to metallurgical problems. Volume 1, Chemical and Thermal Principles; Problems in Combustion. 238 pp. \$2.50.

Volume 2, Iron and Steel. 236 pp. \$2.50.

Volume 3, Non-Ferrous Metals. 197 pp. \$2.50.

PRINCIPLES OF METALLURGY, By C. H. Fulton.

Discussion of alloys, measurement of high temperatures, slags and mattes, etc. The first American work devoted to the fundamentals of this science. 544 pp. \$6.

Mining

HYDRAULIC AND PLACER MINING, By E. B. Wilson.

A complete treatise on the removing of earth by the power of streams of water. 425 pp. \$3.50.

THEORY AND PRACTICE OF ORE DRESSING, By E. S. Ward.

A complete work on the treatment of ores by concentration processes at metalliferous mines in western America. Text closely related and fully cross-referenced to wide range of valuable tables and working drawings. 426 pp. \$4.

Printing and Publishing

THE AMERICAN HANDBOOK OF PRINTING.

A valuable encyclopedia of all branches of printing in concise form. 300 pp., illus. \$2.70.

PRINTING FOR PROFIT, By Charles Francis.

A book on the management of a printing plant based on varied practical experience. 404 pp. \$3.

Book Department, INDUSTRIAL DIGEST

25 West 45th Street, New York City

INDUSTRIAL CALENDAR

Secretaries of Associations are invited to send us the dates of their conventions as early as possible so that their conventions may be properly listed below. When especially requested by Association Secretaries, we will send dates and other available notices concerning meetings of other associations.

- May 15-17. *National Assn. of Mfrs. of the U. S.*, New York City. (G. S. Boudinot, Secretary, 50 Church St., New York City.)
 May 15-19. *American Water Works Assn. of New York*, Annual Convention, Philadelphia, Pa.
 May 15-19. *National Electric Light Assn.*, Atlantic, N. J. (L. W. Shugg, Director, 29 W. 39th St., New York City.)
 May 15-20. *Chamber of Commerce, U. S. A.*, Washington.
 May 15-20. *Exposition of the National Assn. of Purchasing Agents*, Exposition Park, Rochester, N. Y. (H. R. Hedon, Secretary, 19 Park Pl., New York.)
 May 16-18. *United States Chamber of Commerce*, Washington, D. C.
 May 16-19. *National Association of Sheet Metal Contractors*, Indianapolis, Ind.
 May 16-20. *The American Federation of Arts*, Annual Convention, National Museum, Washington. (Richard F. Bach, Secretary, Metropolitan Museum of Art, New York City.)
 May 18-20. *National Retail Coal Merchants' Assn.*, Drake Hotel, Chicago, Ill. (Joseph E. O'Toole, Secretary, South Penn Square, Philadelphia, Pa.)
 May 18-20. *Office Managers' Association*, Washington, D. C. (F. L. Rowland, Secretary, Gilbert & Barker Mfg. Co., Springfield, Mass.)
 May 19. *American Institute of Electrical Engineers*, Annual Meeting, New York.
 May 19-20. *Knit Goods Manufacturers of America*, Atlantic City, N. J. Annual Meeting.
 May 22. *National Association of Worsted and Woolen Spinners*, Hotel Traymore, Atlantic City. Annual Meeting.
 May 22-25. *International Railway Fuel Association*, Auditorium Hotel, Chicago, Ill.
 May 22-26. *National Association of Hosiery and Underwear Manufacturers*, Philadelphia, Pa. (C. B. Carter, Secretary, 40 South Seventh St., Philadelphia, Pa.)
 May 23-25. *American Iron, Steel and Heavy Hardware Association*, Washington, D. C. (H. Chamberlain, Secretary, Marbridge Bldg., New York City.)
 May 24-25. *National Coal Association*, Congress Hall, Chicago, Ill. (Harry N. Taylor, Chairman.)
 May 24-26. *National Confectioners' Assn.*, Annual Meeting, Wrigley Bldg., Chicago, Ill.
 May 25-26. *American Society for Steel Treating*, Spring Meeting, Pittsburgh. (W. H. Eisenman, Sec., 4600 Prospect Ave., Cleveland, O.)
 May 26-27. *American Cotton Manufacturers Association*, Annual Meeting, Washington, D. C.
 May 31-June 2. *Pacific Coast Electrical Association, Affiliated with N. E. L. A.*, Annual Meeting, Los Angeles, Cal.
 June 5-7. *American Association of Engineers*, Annual Convention, Salt Lake City, Utah. (C. R. Thomas, Secretary, 63 East Adams St., Chicago, Ill.)
 June 5-9. *International Association, Rotary Clubs*, Los Angeles, Cal. (C. R. Perry, Secretary, 910 Michigan Ave., Chicago, Ill.)
 June 5-9. *American Order of Steam Engineers Assn.*, Philadelphia, Pa. (Andrew Lauterbach, 4726 North Warnock St., Philadelphia, Pa.)
 June 5-9. *American Foundrymen's Association*, Exposition Park, Rochester, N. Y. (C. E. Hoyt, Secretary, Marquette Bldg., 140 South Dearborn St., Chicago, Ill.)
 June 6. *American Wholesale Coal Assn.*, Detroit, Mich. (G. H. Merryweather, Secretary, Union Fuel Bldg., Chicago, Ill.)
 June 6-8. *National Association of Master Plumbers*, Fortieth Convention, Detroit, Mich.
 June 6-9. *National Assn. of Credit Men*, Twenty-seventh Annual Convention, Indianapolis, Ind. (J. H. Tregoe, Secretary, 41 Park Row, New York.)
 June 7-9. *National Wholesale Grocers of U. S.*, Chicago, Ill. (M. L. Toulme, Secretary, 6 Harrison St., New York City.)
 June 11-15. *Associated Advertising Clubs of the World*, Milwaukee, Wis. (P. S. Florea, Secretary, 110 West 40th St., New York.)
 June 12-15. *National Association of Retail Credit Men*, Cleveland, O. (W. Reis, Chairman, 15 West 37th Street, New York City.)
 June 12-16. *National Fertilizer Association*, White Sulphur Springs, W. Va. (John D. Toll, Secretary, 1010 Arch St., Philadelphia.)
 June 13. *Music Publishers Association of U. S.*, New York City. (E. T. Paull, Secretary, 243 West 42d St., New York City.)
 June 13-16. *Linen Supply Association of America*, Chicago, Ill. (F. H. Hartless, Secretary, 646 North Parkside Ave., Chicago, Ill.)
 June 14. *National Association of Sheet Metal Contractors*, Indianapolis, Ind. (A. L. Seabrook, Secretary, 261 South Fourth St., Philadelphia, Pa.)
 June 14-16. *International Circulation Managers Association*, Indianapolis, Ind. (C. Eyster, Secretary, "Evening Star," Peoria, Ill.)
 June 19-24. *National Association of Building Owners and Managers*, Bedford Springs, Pa. (H. G. Loomis, Secretary, Omaha National Bank Bldg., Omaha, Neb.)
 June 20-23. *Society for the Promotion of Engineering Education*, University of Pittsburgh; Annual Convention, University of Illinois.
 June 20-23. *National District Heating Assn.*, Cedar Point, Ohio. (D. L. Gaskill, Secretary, Greenville, Ohio.)
 June 21-22. *American Society of Civil Engineers*, Annual Convention, Portsmouth, N. H.
 June 22-23. *National Hardwood Lumber Association*, Congress Hotel, Chicago.)
 June 26-July 1. *American Society for Testing Materials*, Chalfonte-Haddon Hall Hotel, Atlantic City, N. J.

Foreign Events

- May. *General International (samples)*, Trieste, Italy.
 May. *Balkan Fair*, Belgrade, Yugoslavia.
 May. *Second Sample Fair*, Trieste, Italy.
 May. *Good Roads Exhibition*, Shanghai, China.
 May 28-June 5. *Motors*, Prague.
 May to November. *French Colonial Products*, Marseilles.
 June 15-Sept. 15. *Annual Exhibition of Ceramics and Glassware*, Dresden, Germany.
 July. *Fair*, Czechoslovakia.
 July. *Second Near East Sample Fair*, Bratislava, Czechoslovakia.
 July 9. *Universal Exhibition*, Buenos Aires, Argentina.
 July 24-29. *International Tobacco Trade Exhibition and Conference*, London, England.

SEDGWICK

The Reflection of Value

WHEN the product of one company consistently brings a higher price than other similar products, we assume that in the higher priced product there is a greater measure of value.

We assume, usually rightly, that cost is the reflection of value.

That is one way you can judge the relative value of Sedgwick Hand Power Elevators and Dumbwaiters. For 30 years people have been willing to pay more to obtain Sedgwick outfits.

There is, however, a better method of judging the value of Sedgwick outfits. Examine a Sedgwick outfit that has been in constant use for five, ten, fifteen years or longer.

S For lifting and lowering — **SEDGWICK**

In the home, as well as in industry, Sedgwick machines have been in wide daily use for more than a quarter century. Sedgwick Hand Power Dumbwaiters and Invalid Elevators are of greatest convenience and perfect reliability.

During many years of experience we have built thousands of Hand Power Dumbwaiters, Elevators, and Gravity Lifts to meet almost every conceivable condition. Why not call upon all this accumulated data, all our specialized experience, for the solution to your lifting and lowering problems?

SEDGWICK MACHINE WORKS

For 30 Years Manufacturers Exclusively of Hand Power and Gravity Lifting and Lowering Equipment

150 WEST 15TH STREET, DEPT. D, NEW YORK, N. Y. -

NO ORDINARY CHART

This EDEXCO Mechanical Bar Chart Makes Graphics Easy

You should inform yourself about this modern aid to Keeping Graphic Records

EDEXCO Mechanical Bar Charts

Their Easy Operation insures their being kept up-to-date.

Their Neat Appearance commands respect.

Their Brilliant Colors compel attention.

They can be seen across the room.

Permanent Records are secured by periodically taking photographs or photostats from them.

They reproduce well as line cuts or half tones for house organs.

They stimulate the workman or salesman.

They make clear points brought up in board meetings.

HOW THIS CHART WORKS

The bars on this EDEXCO Mechanical Bar Chart are not drawn on paper. Each bar is a ribbon. Each ribbon is wound on a spring drum behind the name plate at the left. The right hand end of each ribbon is fitted with a needle prong. The bars can thus be extended to any length and set there by sticking the needle into the background. This background is EDEXCO cork mount, so that the chart will last indefinitely.

Note the metal name plates at the left permit the easy interchanging of the cards. Notice how one name plate can be used for 1, 2, 3, or more ribbons to show 1, 2, or 3 facts about each item.

The 4-color booklet **MECHANICAL GRAPHS** describes this and other charts you ought to be using.

Sales Managers Use These Charts

Director, Secretary or Treasurer.*

Each business today is headed for a new port:—

"The commonly accepted but traditional and antiquated methods of cost accounting, prevalent in so many plants, are falling down under the pressure of modern manufacturing methods. These accounting methods, disguising as they do the real costs, and presenting instead fictitious costs whose real values are thoroughly concealed, have no place in the modern American intensive production manufacturing plant. *What our managers need is not a cost system whose primary purpose is to lend itself, through the accounting department, to a financial audit, but a cost system which is primarily designed to reveal true costs in time to control them and to prevent them from becoming excessive.*"

THE EDITORS,
Industrial Management.

Methods of production planning, of accounting, and most emphatically of cost determination, perhaps efficient in other days, have now become an inadequate *collection of habits—rut-running habits.*

Can your decisions and policies in meeting present conditions, then, be other than fettered by such habits—these "ghosts of yesterday"?

The solution lies not in revolution, but in evolution; through a fresh point of view and the application of sound economic principles.

Your accounting, costs, production planning and sales, under our consulting supervision (based upon an experience of 30 years) will reveal new profit opportunities. We can arrange a service to fit your particular needs—and pocketbook. "It's time to pick up the pilot." At least, let's talk it over.

Our bulletin, "Straight Talk," an exceedingly informal two-minute chat on management problems, will assist executives who have ambitions to satisfy. Your request on your letterhead will bring a complimentary copy.

Cave Man Stuff

BACK near the beginning of things, our prehistoric forebears would have perished from the earth if they had not understood the science of reading advertising.

The cavemen didn't know much about underwear, hair tonic or phonographs, but they did have to eat. The one who could follow the tracks of the game he hunted, or read the meaning of a twisted leaf or broken twig, was best off in life.

Then, as now, the most consistent reader of advertising was best dressed, best fed and most contented.

There has been something of an evolution in advertising in the last few thousands of years, but the principle is just the same.

The *consistent* reader of the advertisements is invariably best informed on what to eat and where to get it; what to wear and how much to pay for it; what to do and how to do it. He's up on the most important things in life. Consequently he gets most from life.

Throughout the ages, advertising has done much to make life livable and pleasant. We owe it much.

Let's make the most of it.

The Ounce of Prevention

In planning to increase your manufacturing facilities to take care of the anticipated rise in sales—or in reorganizing your factory to secure more production per hour or per dollar—you will be faced with many problems in which our experience will be invaluable to you. It is the function of the appraiser, the accountant, and the engineer to see that manufacturing efficiency is at its height from the *first*—not after the plant has been in operation two or three years.

In business too, the ounce of prevention is worth infinitely more than the pound of cure. We can supply the cure where it is needed, but we specialize on the ounce of prevention.

The Business Weathervane

A Summary of Expert Opinion

The recognized authorities on business conditions, almost without exception, agree that business is steadily improving. The spring "boom" has been discounted and business during the summer is not expected to show any remarkable gains—but all indications point to a slow, sure increase in the volume of manufactures, retail sales and the number of workers employed.

The **Brookmire Economic Service** is of the opinion that, "There never has been a time in recent economic history when all the fundamentals which control business movements were in such striking unanimity, for

so long a time, in their indications of business recovery as today. We have abundant credit at easy rates to finance production; a year or more of production and consumption below normal requirements with, in many instances, a deferred demand of great force, a discriminating consuming market not easily satisfied either in quantity or quality of things needed to maintain a high standard of living; a purchasing power derived from farms and factories which by fall should reach a level justifying expectation of free spending; and, what is more important still, the restoration of brighter and more hopeful psychology, which constitutes in itself not only an incentive but a spur to business progress."

The **Harvard Economic Service** believes that the improvement which may be expected in export business will find its reflection in better business at home. "The strong recovery of exports in March makes it probable that the low point in exports has been passed. Exports of cotton cloth increased nearly 50% over February. Steel production rose to within 10% of normal in March, and unfilled orders of the United States Steel Corporation showed the first substantial advance since the beginning of the depression. In line with

this recovery there was a distinct improvement in the March export trade. Total steel exports increased 55% in quantity over February, and were the largest since March last year. Copper exports registered the largest quantity for any month in nearly two years. Gasoline exports increased nearly 40% in quantity over February. Oil exports, raw cotton and coal also advanced strongly. Exports of wheat, wheat flour, oats and meal, and beef products shared in the advance. Exports of corn increased again, making a new high record of 22,936,000 bushels. There seems little doubt from the March showing that our export trade has now joined the imports in definite up-turn."

According to **The Credit Monthly**: "The factors adverse to prosperous business given by the representatives of different lines of business are for the most part the same, the low price of farm products, general depression, lack of export demand, strikes, the coal situation, unemployment, weather, freight rates. There is some difference in the emphasis given to these factors by the various trades. The businesses in closer touch with conditions in the Middle West and South, emphasize more strongly the inability of the farmers to buy."

The **United Business Service** points out that, "The most important factors in the present business situation are (1) the continued improvement in the outlook for the farmer and (2) the pronounced increase in activity in the building industries."

Dun's Review believes that

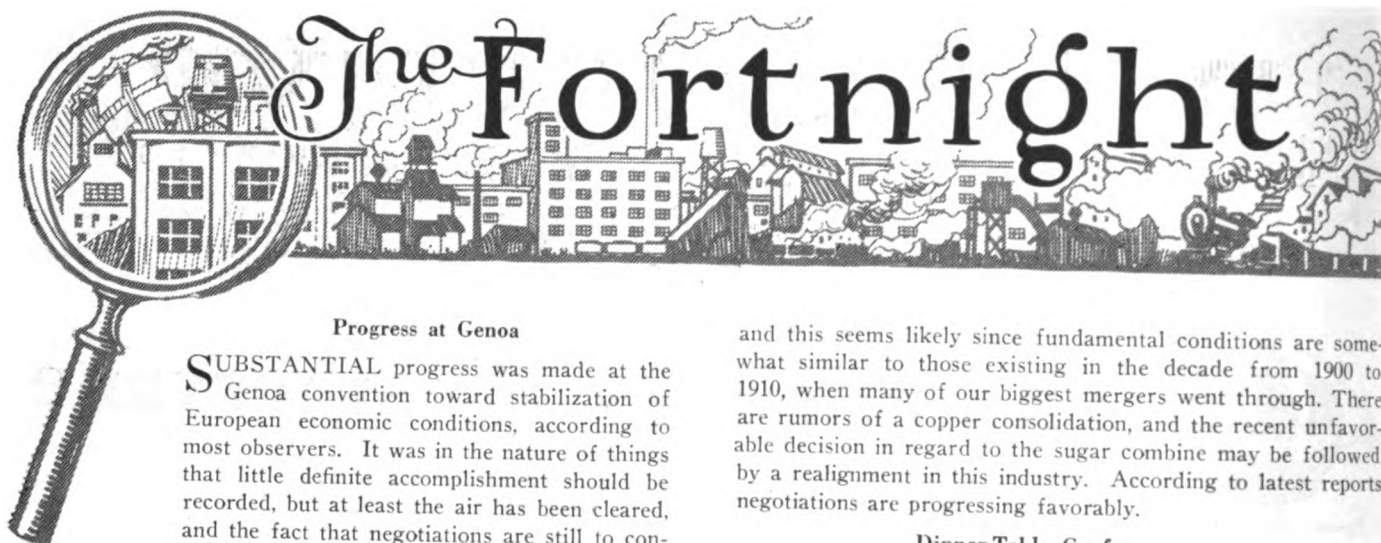

"Practically without exception, basic industries reflect renewed activities, metal, lumber, textiles, hides and leather and other important lines, all disclosing revival, and many prices are at higher levels. Notwithstanding keen competition for orders in different quarters, wholesale markets are more favorable to sellers, and the trend toward firmness may conceivably be carried farther."

(Indianapolis News)

Doctor: — and it never fails.

Progress at Genoa

SUBSTANTIAL progress was made at the Genoa convention toward stabilization of European economic conditions, according to most observers. It was in the nature of things that little definite accomplishment should be recorded, but at least the air has been cleared, and the fact that negotiations are still to continue means a great deal. It is still uncertain

whether the United States Government will take any part in the coming Hague convention, but in any event this country will not be left out of consideration in dealing with the Russian problem. Soviet representatives are reported to be still anxious to enter into business relations with America.

Smoking on Powder Kegs

THE possibility of effecting a sound economic readjustment in Europe under present political conditions will be realized clearly when the six months' non-aggressive pact is considered. If two neighbors made an agreement not to murder each other for a period of at least two weeks, most people would feel justified in locking up both of them. But it is apparent that Europe is sitting on not one, but a number of powder kegs . . . and everybody seems to be smoking.

Export Trade Revival

THE fact that our export trade is showing a steady increase leads many editors to anticipate a corresponding revival in domestic business—a fact which, coupled with the spring spurt in sales, seems to justify a feeling of confidence for the rest of this year.

Steel Consolidations

THE outstanding financial feature of the fortnight was the unexpected consolidation of the Lackawanna Steel properties with the Bethlehem Steel Company. It is possible that this move on the part of Bethlehem will delay the five-company merger which has been in preparation for some time. The decision of the Youngstown Sheet and Tube Company to withdraw from the merger may still further delay the negotiations. Reports that the Bethlehem-Lackawanna group would come into the five-company combine have been vigorously denied. It is rumored that Midvale Steel and Ordnance may be absorbed by the Bethlehem-Lackawanna combination. Naturally, the discussions of steel mergers caused a considerable speculative flurry in steel stocks. All sorts of rumors concerning the eventual line-up of companies are rife.

It is reported that other mergers are under contemplation

and this seems likely since fundamental conditions are somewhat similar to those existing in the decade from 1900 to 1910, when many of our biggest mergers went through. There are rumors of a copper consolidation, and the recent unfavorable decision in regard to the sugar combine may be followed by a realignment in this industry. According to latest reports negotiations are progressing favorably.

Dinner-Table Conferences

THE announcement that the forty-one leaders of the steel industry who dined in the White House recently with President Harding have agreed to the abolition of the twelve-hour workday "if and when practicable" speaks well for the tactfulness of the administration. At the meeting of railroad

presidents which followed, the question of voluntary rate reductions was brought up, and a committee was appointed to take action in the matter. The rate decision of the interstate Commerce Commission is expected at any time now. The attitude of the administration seems to be that railroad executives must accept the Interstate Commerce Commission's decision or face a revision of the Transportation Act, including a repeal of the "return" provision. The Interstate Commerce Commission senses the danger in decreasing rates to such an extent that it would make new railroad financing difficult, and will probably adjust rates with this factor in mind, unless voluntary reductions are announced in advance of the ruling.

Export Loans Repaid

THE financial conditions of large corporations seems to be steadily improving: witness the fact that the International Harvester Corporation has already paid the advance of four million dollars made by the Federal War Finance Corporations for the pur-

pose of financing exports of agricultural machinery. The loan was paid about a year in advance of the maturity date. The advance of five million dollars to the Baldwin Locomotive Works for financing exports of locomotives has been repaid more than eight months before maturity.

Political Straws

THE recent victory of Beveridge in Indiana and Pinchot in Pennsylvania have forced the administration into a realization of the necessity of legislative action on the tariff, bonus and ship subsidy. Definite statements to the effect that both the tariff and the bonus bills will be passed at this session have been made in both houses of Congress. The

(By permission from Forbes Magazine)

The "Help"

U. S.—"I must drop her before she does any more damage."

in Perspective

administration is trying its best to have the ship subsidy legislation passed as soon as possible. The pro-bonus advocates are much disturbed over the political turn.

Smooth Sailing

REPORTS of sales of a large list of leading manufacturers and wholesalers made by the secretary of the National Credit Men's Association show that 78% report better sales, 13% no improvement, and 9% less sales than in the previous month. Coincidentally, the volume of advertising in all types of publications seems to be steadily increasing. A recent issue of the *Saturday Evening Post* carried the largest amount of advertising (figured by dollars invested) ever carried by any publication. Newspapers also report a general increase in the volume of advertising. This should certainly be reflected in increased retail sales.

"Farming Out" Forbidden

THE threatened strike of the railroad shopmen numbering six hundred thousand seems to have been nipped in the bud by the decision of the Railroad Labor Board against the farming-out of repair work. Several railroads had followed the lead of the Erie in letting out contracts for railroad repair work to independent companies in defiance of the Transportation Act. The decision was made in the controversy between the union shop crafts and the Indiana Harbor Belt Railroad. According to the Railroad Labor Board, "no more important dispute has ever come before this board for adjudication." This "bloodless victory" is indicative of what can be done when reason rules.

Stepping on the Gas

THE production of automobiles during the last month closely approach a record and carload shipments are even expected to break previous records—over thirty thousand carloads in the month. Production in Detroit and other automotive centers continue close to capacity, and no slump is expected. Employment conditions in automobile manufacturing centers are considerably improved.

Child Labor Law Ruling

THE recent decision of the supreme court against the constitutionality of the law penalizing manufacturers who employ child labor to produce goods sold in Interstate Commerce will have far-reaching effects. Labor editors join in condemning the decision as a return to archaic working conditions, but trade-paper editors agree that it is a step in the right direction—that of permitting the manufacturer to run his own business without unnecessary interference by Government officials.

Intervention Probable

THE coal strike has not affected business very seriously as yet, despite the fact that more than six hundred thousand men are out of work; but the approaching elections and the underlying political situation make Government intervention likely at any time. It is not improbable that the Government will favor mergers for the coal industry in much the same way that it authorized a merger for the railroads under the Transportation Act.

(Chicago Tribune)

A Dangerous Combination

How Very Awkward!

WHAT'S GOING ON IN WASHINGTON

"Fish, or Cut Bait!"

APPARENTLY the "debate" in the Senate on the tariff bill will continue until the heat of summer and the weariness of night sessions force the matter to a conclusion. One might think that the prospect of dreary sessions would induce the Senators to hurry, even if the need of the nation's business for a decision on this important legislation left them unmoved. But speed and strict attention to duty are among the virtues that the lawmakers apparently do not possess. Absenteeism has been so flagrant that Senator McCumber, sponsor for the tariff bill, was moved to shout at his colleagues:

"If you can't stay here and pass this bill, for God's sake resign and let your State send someone here who will stay here!"

The breach between the House and the Senate over the American valuation plan seems irreconcilable, and the President probably will be called upon to decide the question. Senator Capper, leader of the farm bloc, has expressed complete disapproval of American valuations, on the ground that they will form a cloak for excessively high duties, which, it now appears, the farm politicians are anxious to avoid.

Hoover's Five Conditions

THE annual meeting of the United States Chamber of Commerce occupied the center of the Washington stage for a period during the past fortnight. Herbert Hoover, Secretary of Commerce, told the delegates that the following five conditions must be established in Europe before world trade can go on satisfactorily:

"First, such political relations between the states in Europe themselves as will produce an atmosphere of peace and destroy the atmosphere of war.

"Second, the reduction of armament, not only to lessen government expenditures, but to give confidence of peace.

"Third, the intergovernmental debts, including German reparations, must be fixed upon such a definite basis of payment of interest and principal as will create reasonable confidence that payments will be met.

"Fourth, the balancing of budgets, more through reductions in expenditures than by the increase of taxation; and a cessation of the consequent inflation in currency and short-term bills.

"Fifth, the ultimate establishment of the gold standard with the assistance of either credits or gold loans, and, where necessary, the acceptance of diminished gold content in many old units of currency."

Financiers appearing before the convention said that the United States, willingly or not, must grant liberal extensions of time in the payment of debts owed by foreign governments.

Saved by Ingenious Bookkeeping

OUR own Government ought to take Mr. Hoover's advice about balancing budgets, in the opinion of the *New York Times*, commenting on the address of the Secretary of Commerce. The United States as well as foreign countries, this paper points out, is living beyond its governmental income:

"We escape a deficit this year only by grace of ingenious bookkeeping. Next year Secretary Mellon predicts a deficit of \$484,000,000. That is about five billion francs. The estimated French deficit on the "ordinary budget"—that is, leaving out money spent for reconstruction—is less than four billion. . . . Of marks, \$484,000,000 would be about a hundred and fifty billion. German governmental finance is one of the occult sciences, but it is doubtful if even the German deficit will approach that figure. Finally, our deficit equals a quadrillion or two of rubles, and even the Russians find it hard to think of astronomical sums as big as that."

Lifting Bonds from Business

TWO federal restrictions upon business men—the Child Labor Law and a section of the Future Trading Act—were declared unconstitutional by the United States Supreme Court during the past fortnight. The Child Labor Law was enacted by Congress after the Supreme Court had declared invalid an act which excluded from interstate commerce products in whose manufacture child labor had been used. The law invalidated by the new decision was virtually the same as the old except in that it imposed an excise tax of 10% upon the annual net profits of establishments employing child labor. The court ruled that the tax was intended

to be a regulator of activity rather than a revenue-producer, and was therefore invasion of police powers of the States.

Section 4 of the Future Trading Act, which the court declared unenforceable, proposed to levy a tax of 20 cents a bushel on future trade in wheat. It made exceptions of deals in which the seller is, at the time the contract is made, the actual owner of the property or the renter of land on which the grain is grown, and contracts made by or through a member of a Board of Trade which has been designated by the Secretary of Agriculture as a "contract market."

The Beveridge bombshell in Indiana, followed by the Pinchot high explosive in Pennsylvania, has caused considerable consternation in administration circles, and it is extremely likely that several modifications of policy will follow in order to avoid further internal party complications. The fact that Senator Pepper carried his seat despite the Pinchot victory seems to indicate the growing dissatisfaction over the bonus measure and it is possible that this feeling may result in an executive veto.

The Backward Spring Season

The tremendous scale on which steel processes are conducted is shown by the size of the man at the right. The process of refinement is beginning in the bessemer converter at the left and is nearing completion in the converter at the right. In centre the steel is being cast into ingots. Photographs of steel processes in this issue were taken at the Youngstown Sheet and Tube Co.

The Story of the Steel Mergers

The recent consolidation of the Lackawanna Steel properties with the Bethlehem Steel Company, together with the proposed five company merger, form a new alignment which will have a tremendous effect in the steel industry

IF you make sausages in Chicago, buttonholes in New York, electric cranes in Wisconsin, or anything anywhere, you are interested in steel. It is in the machines that turn out your product, and in the walls of your factory, even if it is not a part of your product itself. Steel is the framework of industry, and therefore any important event in the steel trade is important to you. The consolidations of great steel companies now being negotiated may some day determine the kind of meat you eat for dinner and the style of clothing your wife can wear.

It is estimated that all the steel works in the United States can produce 50,444,000 tons of ingots a year. The capacity of the U. S. Steel Corporation is about 45 per cent of this. The rest is made by fifteen or twenty independent corporations. Two of these independents, the Bethlehem Steel Corporation and the Lackawanna Steel Co., producing about 10 per cent of the total, have just been merged. Five other big independents, with a combined production of about 13 per cent of the total, are considering amalgamation. The proposed merger started with the inclusion of six companies, but on May 19 the Youngstown Sheet and Tube Co. withdrew. It is believed, however, that this "defection" will not stop the merging of the remaining five companies in the group. It is rumored that the Bethlehem-Lackawanna combination may unite with the other merging independents, forming a corporation with 23 per cent of the company's capacity.

What effect will these mergers have upon the industry of the nation? Will the efficiency of the steel trade be increased? Will two great steel companies emerge that will make war upon each other and slash prices, or will they combine quietly to keep prices up?

Let us consider first the merger that is already completed: that of the Lackawanna company with the Bethlehem corpo-

ration. The Lackawanna works at Lackawanna, N. Y., can produce about 1,480,000 tons of bessemer and open hearth steel ingots a year, which, added to the 3,200,000 which Bethlehem can turn out, makes quite a considerable quantity of steel. Lackawanna's rolling mills can make the following finished and semi-finished products:

- 170,000 tons of sheets, bars and small billets
- 500,000 tons of rails
- 225,000 tons of structural shapes
- 150,000 tons of sheared and universal plates
- 277,000 tons of merchant bars and wire rods
- 19,000 tons of bolt and spike rods, which the company's own factory converts into 190,000 kegs of railroad spikes, nuts and bolts.

The addition of Lackawanna's substantial capacity for steel rails will materially strengthen Bethlehem's position in that market. Bethlehem now ships a large proportion of its rails to the South, whereas Lackawanna supplies New England and the Lake States. The consolidated company will therefore have a share in the rail markets of two important sections.

Lackawanna's capacity for bars will also fill a need which the Bethlehem corporation, according to E. G. Grace, its president, has felt for some time. The amalgamation will also give Bethlehem a market for structural shapes in a territory which it has not reached in the past. Mr. Grace, in announcing the merger, said that the acquisition of the Lackawanna "fits in nicely with the plans that Bethlehem has for the future." When he was asked if Bethlehem intended to take over any other properties he said he had nothing to say on the subject, but that the corporation intended to grow as fast as opportunity permitted.

The original announcement of the six-company merger, including the Youngstown Sheet and Tube Co., created a wide furor in financial and industrial circles. All hope of Youngs-

Like large soup ladles—only different. In this open hearth steel furnace the metal is drawn from the furnaces at the right in ladles holding 100 tons each, and then cast into ingots. A test bar for laboratory purposes is being poured by the man at the left.

town still joining the group has not been given up, and the following paragraphs indicate the far-reaching importance of such a six-company "line-up." The six companies involved in this proposed consolidation, with their capacity, as estimated by *Iron Age*, are:

	Ingot Capacity (Gross Tons)	Percent of Country's Total
Midvale Steel & Ordnance Co...	2,894,000	5.74
Youngstown Sheet & Tube Co...	1,500,000	2.98
Republic Iron & Steel Co.....	1,395,000	2.77
Inland Steel Co.....	1,000,000	1.98
Steel & Tube Co. of America...	900,000	1.79
Brier Hill Steel Co.....	600,000	1.19
	8,289,000	16.15

According to *Iron Age*, these are the main facts concerning the markets in which these companies compete:

Midvale has rail mills and Inland is now completing a rail mill which will figure in the rail trade of 1922. All seven companies have plate mills, the most important of these in the sheared plate trade being the Coatesville mill of Midvale. Structural shapes are rolled by Midvale and Inland. Republic and Midvale lead in the production of bars, while Inland and Youngstown Sheet & Tube also have considerable bar capacity. Youngstown Sheet & Tube also have been the principal producers of sheets, but Brier Hill is also a good-sized factor in the sheet market, and the Republic in 1919 acquired the sheet mills of the Deforest Sheet & Tin Plate Co., of Niles, Ohio. In wire products the Youngstown Sheet & Tube Co. and the Cambria works of Midvale have figured in an important way. In wrought pipe Youngstown Sheet & Tube, Republic and the Steel & Tube Co. of America are the largest of the independent producers. Some of the plants of the seven companies roll billets and sheet bars for the market, and in addition to the leading forms of finished material mentioned above the consolidation would have a great range of smaller products such as rivets, nuts and bolts, spikes and miscellaneous track supplies, besides a variety of cold-rolled and cold-drawn products.

Most of the six companies hold large coal territories, so that the consolidation will probably have a sufficient coke supply without going into the outside market. Their iron ore reserves also are considerable. The company holding the smallest supply of ore has enough to keep it going for about ten years, and the largest has about a thirty-year supply.

These holdings are principally on the Mesaba range of the Lake Superior region, although four of the companies have extensive properties on the older ranges also. Five of the directors of the Midvale company are also on the board of the Mesaba Iron Co., whose holdings on the Mesaba range are estimated to contain 500,000,000 to 600,000,000 tons.

Resuming, *Iron Age* says:

With three large plants in the Youngstown district, two in the Chicago district, one at Buffalo and the operations of the Midvale company carried on in both eastern and western Pennsylvania (Johnstown, Coatesville and Nicetown) the consolidation would have the advantage of a number of strategic locations. In particular the inclusion of the Inland Steel Co. and the Steel & Tube Co. of America, which have nearly all the merchant steel capacity in the Chicago district outside of the Steel Corporation, would give the consolidation the same access to Western markets which the building of the Gary plant was intended to secure for the Steel Corporation.

Merger Means Economy

THOSE who are putting the merger through consider that the consolidated companies will be able to reduce overhead considerably by combining organizations. They also expect to be able to effect real economies by treating the entire production of the companies as one unit. When the demand falls off they will be able to shut down one plant and keep another running full time, whereas two competing companies, each owning one plant, would have to keep both going at half capacity. High transportation costs are a further incentive to consolidation. To compete with the U. S. Steel Corporation in any market an independent company must have plants near that market, and the consolidated companies will, of course, be able to serve more markets than they could serve individually.

In looking for meanings in the present steel mergers, it is natural to attempt a comparison of the present time with the great period of mergers which resulted in the formation of the U. S. Steel Corporation. Such comparisons are dangerous, because they often lead to the assumption that what happened in the past will repeat itself. As a matter of fact, conditions in the United States are now so different from those that prevailed at any other period in its history that it is unsafe to predict the future from the past.

When Carnegie Prevailed

SOME similarities between the two periods may, however, be found. The country was then, as now, recovering from a severe depression, that of 1893. The steel industry was dominated by one big concern, the Carnegie Steel Co., although its domination was by no means as complete as that of the U. S. Steel Corporation today.

As the country recovered from the depression, great steel companies were formed with heavy capitalizations—often heavier than the circumstances warranted. Among the most eminent were the Federal Steel Co., the American Steel and Wire Co., the American Tin Plate Co., the National Steel Co., the National Tube Co., the American Steel Hoop Co., the American Sheet Steel Co., the American Bridge Co., and the Illinois Steel Co. Following the example of the Carnegie company, most of these organizations tried to be as self-sufficient as possible, buying ore lands, coal lands and railroads to supply their needs. Nevertheless, they were largely dependent upon one another. Carnegie, Federal Steel and National Steel confined themselves, for the most part, to the production of ingots, billets, bars, plates and slabs, which required further manufacturing before they could be used. The other companies, such as American Steel and Wire, American Tin Plate, National Tube, American Steel Hoop and American Sheet Steel, bought the products of these primary producers and made them into finished goods.

The Steel War

ALL these companies aspired to independence. The reaction in the steel market which occurred in 1900 intensified these aspirations. American Steel and Wire bought two thousand acres of coal lands and ore properties with an annual output of 916,000 tons, and began to install mills capable of performing all steps in the process of making wire. Other producers of finished goods adopted similar policies.

Federal Steel and the Carnegie company began to retaliate. Federal threatened to build wire mills unless the steel and wire company gave up its project to make rods. Carnegie announced that it would build a tube mill at Conneaut, Ohio, sheet mills at Homestead and mills for other finished products in the Pittsburgh region.

The results of this threatened competition would obviously be ruinous to most of the concerns involved, says Abraham Berglund in his book on the U. S. Steel Corporation. Heavily overcapitalized, as most of the companies were, and fortified by very inadequate reserves, such competition would mean decreasing profits and the passing of dividends. As a consequence of this there would be a heavy fall in the value of steel stocks. Industrial warfare, too, demands new appliances, and these could only be secured by issuing bonds or by increasing the floating debt. The interests in control of the consolidations strove in every way to avert the impending calamity. Coupled with these interests were the interests of the underwriters and promoters who still held large amounts of stock which they had been unable to sell to the public, and thus to reap the large profits upon which they had counted. The decline in the value of these securities, owing to the temporary reaction in the steel trade, made their sale still more difficult in the face of a competition which threatened to overwhelm the new companies. The promoters, underwriters, and original owners of the plants, therefore, were all vitally interested in preventing a break in the harmony of the various steel interests.

The New Era

AFTER the election of 1900 steel prices began to move up again, and it appeared that if the several companies did not cut each other's throats they might all make good profits. The result was the consolidation of Carnegie, Federal Steel, National Tube, American Steel and Wire, National Steel, American Tin Plate, American Steel Hoop and American Sheet Steel, forming the U. S. Steel Corporation. Other companies later entered the combination, which is now the largest industrial organization in the world.

Such are the facts of the steel mergers, past and present. Will the present period develop even greater combinations than arose in the past? Or is a hard-fought and widespread steel war looming in the near future?

As practically all the steel business in the country will be divided among three groups (comprising the United States Steel Corporation, the new five-company group and the Bethlehem-Lackawanna consolidation) will steel prices be stiffened on account of the lack of competition? Or, as most observers believe, will the increased efficiency due to centralized control, more than offset any such tendency and probably result in a slightly lower price?

As though steel were ribbons. A blooming mill on which steel ingots, after being reheated, are rolled down into blooms for further rolling into slabs, billets and sheet bars.

Are More Mergers Coming?

The Bethlehem-Lackawanna merger and the reported five-company merger in the steel industry may be the forerunners of many other consolidations

"ONLY by prompt action can the nation be saved from irreparable injury," declared Senator La Follette on May 12 to his colleagues in the United States Senate. Any one unfamiliar with the easy flow of startling language at the command of many American statesmen might believe that the Senator had been privately informed of the approach of an invading army. He would find, however, that the danger to which the Senator referred was merely the proposed merger of independent steel companies, an investigation of which was ordered on Mr. La Follette's motion.

The Senator's sensational statement is important only because it typifies the attitude of a certain type of politician toward attempts at business consolidation and co-operation. It is this attitude, backed up by a real but vague popular demand for the regulation of big business, that has resulted in the confusing anti-trust laws under which industry is carried on.

Apparently we are entering a period of increased co-operation in industry. Co-operative trade associations are now the subject of widespread discussion. The talk of the steel merger has set loose great numbers of rumors of consolidations in other trades; and although the talk is undoubtedly exaggerated and due to some extent to the activity of speculative imagination in Wall Street, still there is probably some fire behind all the smoke. Economic conditions are favorable to consolidations. We are emerging from a period of depression in which the weakest concerns were eliminated, and we seem to be on the edge of an era in which business will be better, but not so good that it cannot be ruined by cut-throat competition. These circumstances are not entirely dissimilar to those which resulted in the great period of mergers at the end of the nineteenth century and the beginning of the twentieth.

Legal Entanglements

AT the same time we are living in a period when the laws governing business consolidations are more confusing than ever before. The Sherman, the Clayton and the Federal Trade Commission acts, the various State and anti-trust laws and the great mass of conflicting court decisions in which they have been interpreted, form a legal labyrinth so involved that no one can tell where he stands in it. In spite of the lessons in co-operation which this country learned during the war, these laws still stand, as restrictive and confusing as ever.

Shortly after the armistice was signed Charles H. Sabin, president of the Guaranty Trust Co. of New York, made a statement on this subject. He pointed out these truths:

We should liberate ourselves from the chains of legal antiquities and absurdities such as the Sherman anti-trust law. The war has taught us that competition and individual action must yield to co-operation and co-ordination. We should likewise recognize that freedom includes the liberty to combine as well as to compete.

Certainly, the national crisis through which we have just passed has proved beyond even the shadow of a doubt that if the Sherman law is not legally unconstitutional it is most assuredly economically and logically "unconstitutional" and should be repealed. In the last year and one-half we have witnessed the strange anomaly of the Government itself practicing methods which it had decreed unlawful; but only by this could we have won the war. And we have seen Congress lately lift the ban imposed by the Sherman law in so far as foreign trade is concerned by enacting the Webb bill, which wisely permits combinations of American business interests in the foreign field and opens up great opportunities.

That was a wise step forward, but it did not go far enough. Congress should substitute for the Sherman law a statute based on the elimination of economic waste, which, truly understood in its broad application and justly administered,

would adequately protect every interest, and, most of all, the interests of the people. Such a statute would not permit monopolistic combinations organized for the restraint of trade and for greed. It would not allow the strong to crush the weak. It would not countenance a wasteful overproduction, ruinous competition and destructive price-cutting. It would be based upon an ideal of service rendered to the public as a whole, and by that measure it would permit legitimate business to fulfil its destiny of greatest usefulness.

Business men do not ask that restrictions upon industry be removed entirely. They know that in the interests of the country some regulation is necessary. Not all combinations are beneficial and efficient.

This fact is worth bearing in mind, not only in connection with the legal regulation of combinations, but also in judging the effect of consolidations upon the business situation and in estimating the investment value of securities involved in mergers. Not every union of companies in an industry works properly. Some trades do not lend themselves to large consolidations. Sometimes mergers are effected under favorable cir-

Puzzle

How to Let Out the Tame Ones and Keep in the Wild Ones.

cumstances and are ruined by the greed of their promoters, who burden them with excessive capitalization for speculative reasons.

A great many big corporations were formed in the merger period of 1900-1902, but have since disappeared. Others came into being so handicapped that they are only just now finding a sound basis. The American Bicycle Co. is one of those which was built on an insecure foundation and which dropped out of the running. Before its formation bicycles were manufactured by a great many small companies. Their product became a fad, and by vigorous competitive advertising and aggressive selling they built up tremendous sales and large profits. The promoters of consolidations thought that this was an opportunity for a big clean-up. But in organizing the American Bicycle Co., which was intended to dominate the field, they upset the situation that had made it possible for small companies to prosper. When competition passed and heavy advertising was dropped, the fad for bicycles also passed, and the company failed.

Plenty of these unsuccessful "trusts" came, but soon dropped out of sight. Among them were the American Malting Corporation, the Distilling Co. of America, Standard Rope and Twine, and International Power. Many others, including the American Locomotive Corporation and American Ice, struggled for years to overcome the effects of the excesses of their original sponsors.

American Can, which is now a strong corporation, was an outstanding example, according to Richard D. Wycoff, who describes its vicissitudes in *The Magazine of Wall Street*.

The object of its promoters was to control the industry and get a lot of common stock which they could sell. They did this by filling every bid so that the stock eventually sold at something like \$2 a share, where it lay for years. Although twenty years of age, this company has not yet paid its initial dividend, but it appears to be approaching that point. Twenty years have been required to overcome the sins of its promoters.

When Mergers May Succeed

EXPERIENCE shows that certain economic conditions are necessary to successful consolidation. Mergers are best effected in industries which manufacture a standard product for which there is a wide general demand. In order that large-scale production (one of the chief advantages of consolidation) may be most efficient the machinery used by the industry must be large and expensive. Heavy capitalization is then a great advantage. The steel industry, in which blast furnaces cost half a million dollars or more each to build and requires a capital of a full million to maintain and operate, is an outstanding example of this.

If an industry is such that freight charges are an important item in the cost of delivering its product, it lends itself to

A warm brew is mixed in this caldron. Steel from this giant electric furnace becomes tool steel at the Atlas Crucible Steel Co., Dunkirk, N. Y.

(© Galloway)

successful exploitation by large corporations, for big concerns can locate plants at will in the most advantageous situations, and often can control transportation systems for their own benefit. For similar reasons, the existence of large bodies of raw material in centralized locations also make mergers advantageous.

One trouble with our anti-trust laws is that they do not take these business truths into account. They are based, not upon a consideration of economic facts, but upon the prejudices of politicians, whose eyes are upon the next election rather than upon the welfare of the nation's business. Economic waste goes on in spite of them, while combinations that would be beneficial are often checked or driven to underground channels. The remedy is not the removal of Government regulation, but

the revision of the regulatory laws so as to conform more closely with economic laws.

The present agitation for the clarification of the laws governing trade associations, which is being encouraged by Secretary of Commerce Hoover, may result in a revision of the anti-trust laws that will make things easier for combinations of all kinds. A program for such a revision has been outlined in the *New York Evening Post* by Henry R. Seager, an economist of high repute who from 1914 to 1921 was a member of the Federal Trade Commission of the United States Chamber of Commerce.

Desirable Regulation

MR. SEAGER, like Mr. Sisson, believes that trade associations in other fields than exporting should be permitted to co-operate in stabilizing prices, under suitable limitations:

Some degree of regulation will no doubt prove necessary, Mr. Seager said, if we follow the precedent set by the export trade and the farm co-operation acts and permit co-operation even with reference to prices in other industries. It will be more in harmony with our traditional policy to look for such regulation not through Government ownership and operation of industry, but through an agency like the Federal Trade Commission, reorganized and expanded for this purpose, just as we are attempting the regulation of the railroads through the Interstate Commerce Commission.

Three different kinds of regulation are necessary, in Mr. Seager's opinion:

Regulations insuring adequate publicity with reference to prices and costs and all related aspects.

A further development of the machinery already in existence for enabling the commission to put a stop to unfair methods of competition.

An enlargement of the power of the commission to permit it to declare, when the facts so warrant, that prices established by joint action were unfair and unreasonable, and to require the substitution of fair prices, subject, of course, to court review, as are rate decisions of public service commissions.

Business men may or may not approve of Mr. Seager's

Flirting—at long distance—with terrible heat. Pipe couplings are forged from genuine hand-puddled iron; couplings for the largest sizes being made on powerful hammers as seen at left.

program in its entirety. The last provision, which would give the Federal Trade Commission rather drastic control over prices, will probably arouse considerable disapproval. The general idea in Mr. Seager's mind, however, seems to be the elimination of a general provision against combinations, and the substituting of machinery which will prevent the use of unfair trade practices by combinations. This is a modification which should certainly meet with the approval of business men.

The Senate is now considering a bill, introduced by Senator Edge, which embodies to a large extent the ideas of those who have been agitating for a clarifying modification of the anti-trust laws. This bill provides that the Federal Trade Commission, upon application of a trade association, may pass upon the legality of the association's activities, and if it is

satisfied that all is well, issue a certificate which will protect the association from prosecution under the anti-trust laws. When it receives an application for a ruling, the Commission may, if it wishes, call a conference of leaders of the industry in which the association operates, in order to formulate binding rules regarding fair trade practices in that industry. The bill also provides that associations must file with the Commission complete statements of their activities and copies of all statistics which they collect, and the Commission will have the right to make public any of the information filed with it except "trade secrets" and the names of customers.

This Edge bill, if passed, will, of course, provide only very slight relief from the confusion of the anti-trust laws. Still, its existence is a hopeful sign.

The Progress of Business "Cycles"

SEVERE depressions in business are represented by the curve of the line below the indication, "Normal Conditions in Business." It is such periods of depression, with their consequent waste of capital and labor, that Secretary Hoover would have us avoid through the employment of more efficient and economical methods of production and distribution. Had industry in general been 30% more productive, a possibility which is

claimed for it by the Secretary of Commerce, it is evident that the periods of depression which have marked the past two decades would have been less frequent and certainly less severe. In other words, the great fluctuations in business which have occurred more or less regularly in that period have not exerted a wholesome influence and could have been avoided through national co-operation. —*Magazine of Wall Street.*

Unemployment Steadily Decreasing

Survey by the Associated Press reveals return to normal conditions

GENERAL improvement in the unemployment situation is indicated in reports gathered by the Associated Press from Federal, State, Labor and industrial leaders. The survey was unusually thorough and a résumé is given herewith.

Delaware—Applications at federal employment bureau, Wilmington, drop from 250-300 daily to 10-15 daily.

Illinois—Ratio of applicants to jobs, as reported by free employment offices has recently decreased from 174.4 to 100 to 216.3 to 100.

Kansas—Number of unemployed reduced at least 3,000, according to John H. Crawford, labor commissioner of the Kansas industrial court.

California—Total of unemployment 7 to 10% less than at this time a year ago, according to John H. Crawford, federal and state labor commissioner of the Kansas industrial court, and labor officials.

Ohio—Conditions improved 40% in last year; placement by employment offices during first quarter of 1922 46% more than at this time a year ago, according to federal and state and labor authorities.

Oklahoma—Unemployment lessened one-third to one-half, according to a recent report of Claude E. Connally, the state commissioner of labor.

Wisconsin—Fifty per cent more persons placed by employment offices recently than during last few months.

East and Southern New York—While no official state statistics on the number of unemployed were available, it is estimated that conditions are much improved.

New Hampshire—State Labor Commissioner John S. B. Davis said that New Hampshire business was recovering very slowly, with the exception of the metal trades.

Vermont—Aside from the granite strike, the labor situation was not regarded as alarming, according to officials of the Associated Industries of Vermont. It is explained that while some industries have been rather hard hit during the last year, employees have shifted to others which are active.

Pennsylvania—"Industrial depression virtually is at an end in Pennsylvania," Clifford B. Connelly, Pennsylvania commissioner of labor and industry, declared. "During April building operations in every section of the state have brought a market shortage of skilled workers in the building industry. In Pittsburgh, Erie, Harrisburg, Johnstown, McKeesport and Philadelphia iron and steel plants are operating between 50 and 75% of normal."

Kentucky—Pat Filburn, assistant federal director of employment and labor, declared at Louisville that there are about 5000 men without employment in Jefferson county, probably fewer throughout the remainder of the state. The situation has been improving steadily, he said, but a recent influx from other states has added to the number of unemployed.

North Carolina—"The unemployment situation in North Carolina has passed the acute stage," said M. L. Shipman, commissioner of labor. "The demand for unskilled labor has exceeded the supply at several points during last month. The employment service finds difficulty in supplying the demand for farm labor and for common labor in fertilizer plants. Housing conditions show improvement over any other period during the last year."

Alabama—Farm, factory and mine labor is more plentiful and wages are lower than a year ago, according to F. W. Gist, statistician of the Department of Agriculture and Indus-

try. Mr. Gist continued: "Mine production is nearly normal. Last year's output of steel and iron, 13,000,000 tons, will be increased this year to nearly normal—20,000,000 tons."

Louisiana—"The oil sections are overcrowded by workers seeking employment," said F. E. Wood, commissioner of labor.

Mississippi—The demand for labor is 90% of normal and the supply 94% of normal in Mississippi, according to Prof. P. P. Garner, commissioner of agriculture and commerce. For the first time in several years reports to the commissioner's office indicate a sufficient supply of farm labor.

Maryland—There has been a marked absorption of idle workers in Baltimore during the last thirty days, according to A. S. Goldsborough, special agent for the Department of Labor. Virtually 90% of the industries of the state are located there. Mr. Goldsborough added that 8000 persons were still urgently in need of work.

Georgia—Employment conditions in the textile industry in Georgia are considered unsatisfactory, but "the first of May will find a noticeable improvement in virtually all other lines," said Secretary Hixon of the Atlanta Employers' Assn.

Tennessee—A small, steady improvement is reported by the Tennessee Manufacturers' Association.

Florida—Roger Babson, after a tour of Florida, declared the state had not shared in the general depression, and reports received at Jacksonville from all parts of the state were said to show little unemployment. A vast amount of new construction and highway building was said to be in progress.

Illinois—Industry "at last is forging ahead," said George B. Arnold, director of the Illinois department of labor. "Chicago reports are particularly optimistic. Building is really opening up, making a strong demand for steel, iron, brick, lumber and other material."

Ohio—W. J. Biebesheimer, federal director of labor, state department of industrial relations, said a quarter of a billion dollars would be spent in Ohio this spring, which would be directly beneficial to working conditions. State, city and country paving programs will approximate \$50,000,000 in expenditures, he said; soldiers' bonus will put about \$30,000,000 in circulation, and manufacturing concerns of the state, according to information received at this office, have \$100,000,000 ready for spring production.

Minnesota—The three employment offices operating under the Minnesota state industrial commission report an increase in the demand for labor and more difficulty in supplying it. J. D. Williams, of the commission, said warmer weather will bring conditions "somewhere near normal."

Indiana—Of the fifteen largest cities of Indiana, none reports conditions as unimproved; two report employment equal to that of pre-war times, and in only two are conditions giving serious concern, according to Evans Woollen, of Indianapolis, regional director for Indiana of President Harding's conference on unemployment.

Michigan—Slow, steady improvement since fall is reported by Carl Young, state labor commissioner.

Iowa—A. L. Urlick, Iowa state labor commissioner, said labor conditions in Iowa were considerably improved over a few months ago. On December 1, 1921, he said, there were 14,000 more men out of work in the state than now, exclusive of striking miners.

(Turn to page 1037)

How Will the Coal Strike End?

The public seems indifferent but business men realize that unless the strike ends quickly there must be Government intervention
—why not now?

WILL the coal strike be settled through Government intervention? And if a commission is appointed, just what will it be expected to do? Although the miners, operators and the general public are of the opinion that some form of Government intervention will be needed to prevent a serious coal shortage and a consequent slowing down of industry, suggestions as to the probable accomplishments of a commission range all the way from nationalization of the mines to temporary arbitration of the present dispute.

The United Mine Workers favor Congressional action to end the strike at once and a permanent commission to gather the facts and work out a permanent policy for the coal industry. In a recent address, Philip Murray, vice-president of the United Mine Workers, said that the miners would declare the strike off and return to work, pending the negotiation of a new agreement if Congress would pass a joint resolution providing that the award of the Bituminous Coal Commission of 1920 be applied to all soft-coal operations, and providing the recommendation be made that the President call a national conference of the representatives of all operators and mine workers to negotiate a new agreement.

As to a permanent policy for stabilizing the industry, Mr. Murray recommended the appointment of a representative, technical and official commission to collect and analyze all the facts and to make constructive recommendations.

In the opinion of the operators, however, a Government commission needs to be hedged about with various safety-

first devices. According to Professor T. H. Watkins, speaking for the operators: "If a commission finally should be appointed, whatever its character or authority, it should not be clothed with authority resembling compulsory arbitration. It should not be composed of representatives of either miners or operators. It should be a commission composed entirely of representative outstanding public citizens, who first of all have in mind preservation of our present form of government. Cool and calm judgment, careful consideration of the issues involved are necessary on the part of the public, the operator and the miners' leaders."

Ex-Fuel Administrator Speaks

STILL another solution is proposed by Dr. Garfield, former Fuel Administrator. He believes public ownership need not be substituted for the present system, provided "those interested as operators and mine workers will co-operate with the Government, representing the consumer, and agree upon a program of action calculated to secure just results to all concerned." He suggests a plan which was considered early in 1919. According to the *Coal Trade Bulletin*, this plan provides:

1. That two separate federal advisory commissions be established, each having to do with coal—a bituminous commission and an anthracite commission—representing the public, the mine workers and the operators.
2. That the Secretary of Commerce be designated as chair-

The Public May Not be Interested, But—

(The Star Co., N. Y. American)

Watch Out For The Coming Jolt.

(New Orleans Picayune)

Aside from a Few Wicked Poses, This Thing Has
Simmered Down to a Rather Tame Struggle.

man of each commission, to act for the President as the representative of the public.

3. That the mine workers be represented on each commission by, say, three members, chosen by and from their own group, and that the operators be represented by an equal number chosen in the same way.

4. That these commissions have authority to require from the Federal Trade Commission, the Bureau of Labor Statistics of the Department of Labor, the Interstate Commerce Commission and the Geological Survey of the Interior Department all the facts necessary for the determination of policies.

5. That Congress be asked to appropriate sufficient funds to enable the Labor Statistics Bureau to have at all times ready at hand full information as to the cost of living of the mine worker; the Federal Trade Commission, all the facts regarding cost of producing and selling coal; the Interstate Commerce Commission, all the facts showing cost of distribution and the Geological Survey, figures showing the supplies on hand in all sections of the country.

6. That these four fact-finding bureaus of the Government have nothing to do with the determination of policies, their responsibility ending with an impartial ascertainment and presentation of the facts.

7. That the coal commissions, representing the public, the mine workers and the operators have no power to determine policies, but be purely advisory—advisory to the President of the United States, speaking through the Secretary of Commerce as chairman.

8. That with the President of the United States shall

rest the power to determine policies and to make such regulations as may be authorized by Congress upon his recommendations, the action of the President being in every case based upon the advice of the Secretary of Commerce, speaking with understanding as a result of his conference with the advisory commissions and his study of the facts submitted by the fact-finding bureau.

Government Action Is Expected

ALTHOUGH it is said the Administration is in no hurry about intervening in the strike, action of some sort is likely to be demanded within the next six weeks by the manufacturing interests of the country.

And, according to the *Coal Trade Journal*, "When the President's plan for the settlement of the present strike of mine workers and for a settlement of future disputes between the employers and employees in the coal industry is submitted, it will provide for the creation of a standing commission empowered to deal with wage issues as they arise, but for no Government supervision or control over the coal business of the country. It is believed that Mr. Harding and his advisers favor the establishment of a permanent coal commission created by law which would have somewhat similar jurisdiction over the industry as is now exercised by the Railroad Labor Board over the wage issues in the transportation industry." It is also reported that Mr. Harding personally is in favor of what is known as the Kenyon plan, the central feature of which is a commission authorized to put into effect an industrial code for the business of producing coal.

Making Old Oil Wells Profitable

How 6,000,000,000 barrels of oil can be saved from wastage

A NEW frontier struggle is likely to take place in America within the next few years—a battle with nature for the recovery of oil reserves which cannot be recovered by present methods. In a comprehensive article in *Oil News*, Barnabas Bryan asserts that the oil shales of North America could furnish the world with oil for an indefinitely long period. The reason they are not exploited today is that oil is still too cheap. The production of 100,000,000 barrels of shale oil per year would require mining equipment to handle ore twelve times as fast as the Utah copper mines did in 1920, for both stripping and mining, or at the rate of 500 sixty-ton cars per day. It would require crushing, retorting, and condensation equipment to the value of more than \$100,000,000. The refineries would absorb from one to four hundred millions, according to the success attained in refinery practice as applied to shale oils. These costs will not permit competition by shale oil so long as Mexican oil can be imported at prevailing low prices.

From the present indications, however, it would appear that competition from this source can continue for only a comparatively short time. Although there is a possibility of another great pool being found in Mexico, it is doubtful if it will produce more than 150,000,000 barrels or less than the oil exported in 1921. And when the end of the great oil fields in Mexico does come, Mexican production is likely to drop 100,000,000 barrels per year. Although other smaller fields may be discovered, they will be far away from the present oil centers. And considerable expense will be incurred in opening up new territory before it will be known whether or not there is a real chance of money being made from the work. It is estimated that the cost of producing oil in Mexico or South America will then be at least twice that in the United States.

But at present the oil industry in this country is still in the

"high grade" period of development, just as in the early days of a mining camp, all the work done is toward the development of rich ore. Estimates of production have been on this high-grade basis of production. When a well has passed the gusher stage and the gas in the oil no longer has sufficient pressure to force the oil to the top at a paying rate, or when the sand becomes clogged with paraffin or asphalt, the well is abandoned.

Air to Increase Production

EXPERIMENTS by the Bureau of Mines prove that this waste is unnecessary. In old fields where production is no longer profitable, air may be pumped down into some of the wells to increase the production from others. This air dissolves in the oil underground and causes it to act as though the regular oil gas were still present to help force the oil out of the sands. It has been proposed to modify this process by electrically igniting the mixture of oxygen from the air and the oil gas in the sands so that heat will be furnished to increase the flow of the oil and to make the gas, as it comes from the wells, valuable for commercial use. A drill is also being perfected, designed to make lateral horizontal holes out through the asphalt choked area about the wells and thus allow easy channels for seepage from the distant parts of the sands. Many other ideas will, no doubt, be developed as the higher price of oil stimulates work of this character.

Six billion barrels of oil have been produced in America, and it is estimated that an equal amount still exists which may be recovered by the production methods now in use. But it is believed that a greater amount still remains underground in the known fields—enough oil to last at least sixty years, if sufficiently ingenious methods are developed for getting it out of the ground.

Unlocking Alaska's Treasure Chest

Why our richest possession has remained undeveloped and how big industry is today turning northward to this land of industrial opportunity

GREAT BRITAIN and France have become great industrial and commercial nations largely because of intelligent use of their colonies. European countries have developed their overseas possessions as great storehouses of raw materials, and at the same time have used them as markets for home-manufactured goods; for, as a colony develops, it acquires a consuming population. The United States has one possession that it could develop in the manner in which England has developed South Africa and France has promoted Morocco. But we are not making the most of our opportunities to exploit one of the richest territories in the world—Alaska.

Nor can we plead ignorance as an excuse for our failure to take full advantage of Alaska. On the contrary, every government official that is sent there comes back and tells us how much could be made of the country. His report is filed away in the Government archives, an extract of it is printed in the newspapers, everybody says "how true," and nothing is done.

What Alaska Needs

OUR failure to take advantage of our Alaskan opportunity is not due to ignorance as to what action we ought to take. The needs of Alaska, in a general way, are pretty well known and universally recognized. The situation is concisely presented in the 1921 annual report of Scott C. Bone, Governor of Alaska, to the Federal Secretary of the Interior:

Alaska needs capital. Alaska needs people. Its natural advantages are obvious. Its resources are apparent and real. Its opportunities are inviting and manifold.

But a chaotic system of government has repelled capital and retarded growth and population.

Liberalized laws for Alaska and more flexible rules and regulations under such laws, with a concentration of authority and responsibility and an administration co-ordinated and brought closer home, are clearly needed to speed the progress and development of the Territory.

Every governor of Alaska has presented its needs, always in forceful and often in picturesque terms, and some of these needs have been met through piecemeal legislation. But the paramount need of a coherent, constructive, upbuilding Federal policy for Alaska has gone unheeded. Thus, after more than half a century—the victim of inattention at Washington and the prey of visionaries and theorists—Alaska's destinies have come to be intrusted largely to multitudinous, overlapping bureaus, admirable and efficient in their personnel, but confusing and complicating in their operation.

Individual initiative, which is essential to substantial development in any country or community, new or old, has been halted and the pioneer spirit maimed. Alaska has made progress slowly under these heavy handicaps.

Governor Bone points out that all his predecessors have shown Alaska's needs. Apparently every man who is sent there, after he has had a chance to look the situation over, holds his head in his hands and wails, "What a shame it is that such a remarkable property should be so wofully mismanaged!" and then puts all the skill at his command into the task of explaining his feelings in his report. Thomas Riggs, Jr., who was Governor Bone's predecessor under the Wilson administration, was just as emphatic as Governor Bone in his condemnation of our policy toward Alaska. Riggs was particularly annoyed by the contrast between American stupidity in colonial administration and British efficiency. In his 1920 report he wrote:

Change of Viewpoint Imperative

IN Canada the founder of a great new industry gets knighted—in Alaska, very often, indicted.

We have at present no colonial policy such as has been evolved by our British neighbor. The pessimistically inclined cannot understand why population is not rapidly increasing, and take this as an evidence of industrial decay. Nothing is further from the truth. Industry, where established, is progressing, but the many federal prohibitions, probably enacted for the benefit of an ideal conservation, do not make for conservation.

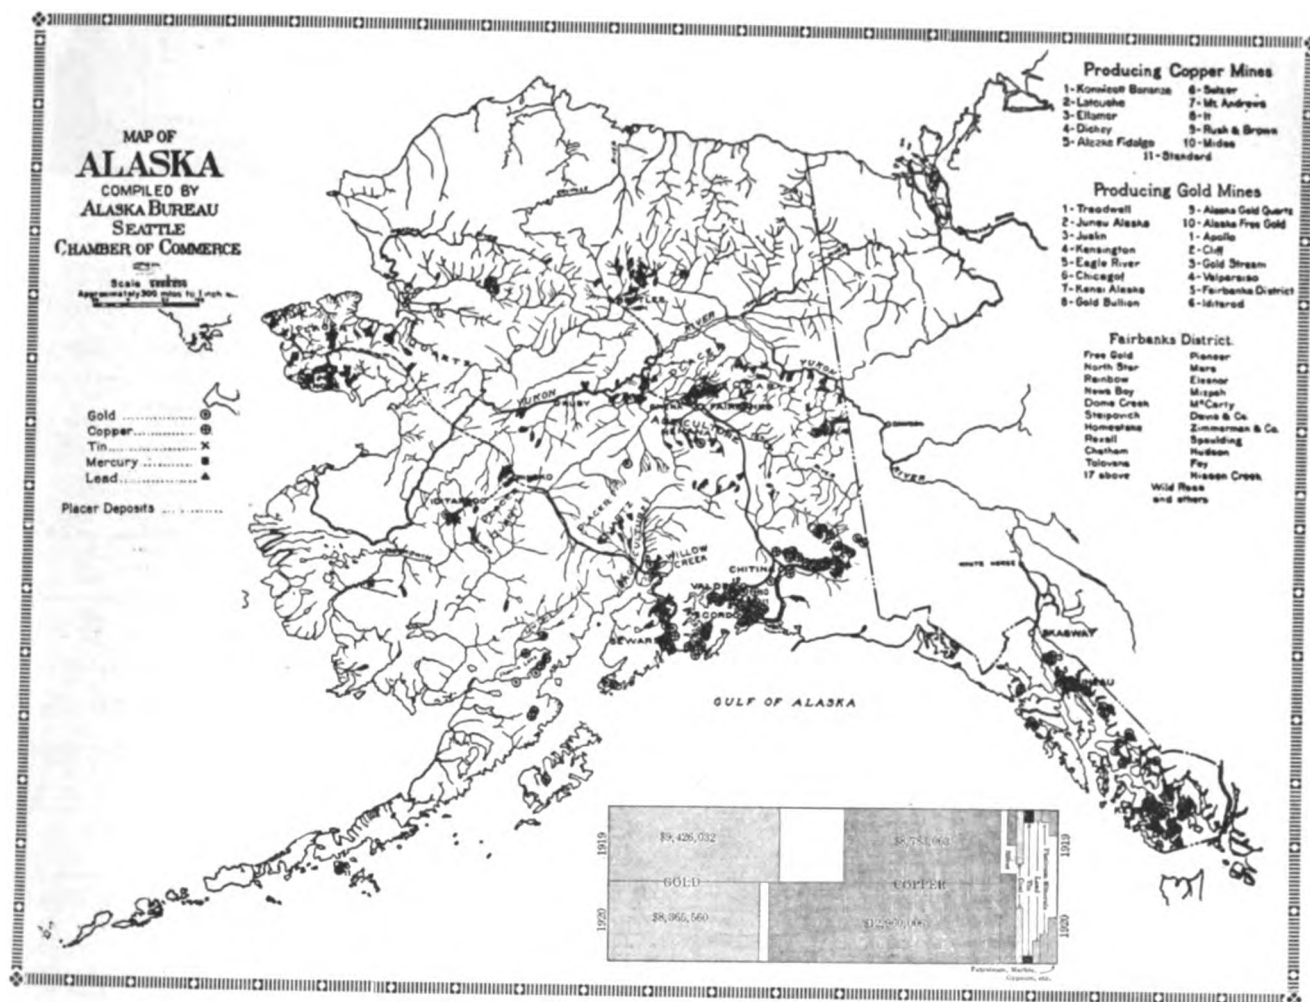

There have been honest attempts to open up Alaska by the Government, principally in the construction of the Government Railway from Seward, on Resurrection Bay, to Fairbanks, on the Tanana River, but in the meanwhile little attention has been paid to the proper development of the great natural resources. The fisheries, with their annual output of approximately \$50,000,000, have been subjected to overfishing until the industry faces exhaustion; the national forest regulations, while becoming yearly more enlightened, still contain provisions which capitalists view askance when asked to make heavy investments in pulp and paper factories.

Just what are the resources of Alaska that have been so neglected? We will never know how much they are really worth until we develop them. But some idea of their extent may be gained by an examination of what has been done with them so far.

Mining began in Alaska in 1880, and between that time and 1920 the mines of the country produced minerals to the value of \$461,474,789. Ninety-six percent of this came from the gold and copper mines. Gold, as is well known, occurs in widely scattered parts of the Territory. The placer gold mines of Alaska have produced \$217,885,000 worth of ore. The industry is now in a state of decline, but Governor Bone believes that when operating

Millions of dollars worth of copper have been mined in Alaska. Here is the famous Kennecott mine at Kennecott.

Map of Alaska Showing Mineral Resources

Production of minerals in Alaska in 1920 amounted to \$23,307,759, as compared with \$19,620,913 in 1919. The gain was entirely due to the copper output, which jumped from 47,221,771 pounds to 70,435,363 pounds, though the number of copper mines decreased from 11 to 8.

costs have been reduced by the advent of cheaper freight rates and supplies placer mining will be stimulated once more. This industry, like all the others of Alaska, is tremendously handicapped by lack of transportation facilities.

Alaska's Copper Mines

MORE important, from an industrial standpoint, are the copper mines. Eight copper mines were operated in Alaska in 1920. These are estimated by Governor Bone to have produced about 766,095 tons of ore, from which 70,435,363 pounds of copper, 682,033 ounces of silver, and \$18,868 worth of gold were recovered. This brings the total copper production of Alaska during twenty years of mining up to 615,442,699 pounds. More than half of this is the output of the past decade. As in the past, the only large copper production in 1920 was from the mines controlled by the Kennecott Copper Corporation, one of Prince William Sound and three in the Kotsina-Chitina district.

A number of new discoveries of Copper ore were made in 1920 in the region tributary to the Government railroad, but there were no important developments.

It must be remembered that this production of copper represents only a scratching of the surface. It cannot be repeated too often that Alaska has not adequate road, railroad and steamship facilities to transport her goods economically. Only the most favorably located mines can be used because it costs too much to ship the copper from the others.

Other metals produced by Alaska are tin—the only deposits

on the continent—antimony, lead graphite, cinnabar, palladium, platinum and molybdenum. The output of these metals is at present very small, but it is impossible to predict how they will develop when the country is really opened up. The prospects of the tin industry especially are great. Much tin plate is used in the Alaskan fish canneries, and this demand may stimulate the establishment of tin smelting works on the Pacific Coast of the United States or perhaps even in Alaska itself. At present nearly all the tin ores of the world go to Europe and the Atlantic States for reduction. Heavy transportation costs are naturally involved, and the establishment of a tin industry on the Pacific Coast would effect great savings.

The non-metallic mineral resources of Alaska have not been much developed, but they appear to be great. They include gypsum and barytes, and marble which is said to be equal in quality to that of Vermont.

Oil in Alaska

THERE has been great activity in prospecting for oil in Alaska since that passage, on February 25, 1920, of an act regulating such prospecting. Four hundred and ninety four applications have been filed, covering 1,100,553 acres. Up to June, 1921, however, the only producing wells were those of the Chilkat Oil Co., which has a daily output of about forty barrels. In the Anchorage district drilling on leased ground reached a depth of 200 feet when it was suspended because of

Building Records Broken

APRIL broke all records for the amount of construction started, according to the F. W. Dodge Company. Contracts awarded in the twenty-seven Northeastern States amounted to \$353,192,000. The previous high record was for July, 1919, the total having been \$317,698,000.

Last month represented an increase of 20% over March and of 60% over April, 1921. The first four months of this year have rolled up a total figure that is just under a billion dollars and is 65% greater than the total for the first four months of 1921.

Flood of New Securities Issued This Spring

In the rise and fall of the two lines may be traced the acute depression early in 1919, following the first attempts to adjust industry to a peace basis; the post-war boom of the later months of the year, extending into the summer of 1920, and the collapse in the fall. The acute demands for capital are seen in the upturn of the line representing new issues in the United States during the spring of 1921, while the falling off in the volume of new issues later in the year resulted from the high interest rates and the unwillingness of borrowers to finance their needs under such conditions. The easing of money rates late in the year brought another large volume of new securities and two months' lull in January and February of the current year was followed by flotations of over \$300,000,000 in both March and April. At present the bond market gives evidences of being in a digestive stage.—(New York Evening Post.)

Analysis of the Commodity Trend

LITTLE or no abatement of the upward trend of prices in the wholesale commodity markets was perceptible last week, 71 advances appearing in the list of quotations compiled by *Dun's Review*, as against 32 recessions, which contrasts with 76 increases and 24 declines in the previous week's statement.

The grain markets were active and strong, wheat being advanced by increased foreign demand, and corn, oats and rye rising in sympathy with the improved position of that cereal. Subsequently, however, wheat reacted sharply. Provisions displayed a steady undertone, and, on the whole, tended upward.

Quotations of iron and steel show increasing strength, as demand has been sufficient to provide producers with a plentiful supply of orders, and about the only effect of the coal strike has been to increase the cost of iron and steel production and to accentuate the price firmness. Cotton goods tend steadily upward, reflecting the advance in the raw material, while a better demand for footwear and other articles made from leather has caused a more cheerful feeling in both hides and leather, and prices of these commodities are firmer.

Without exception, each week this month has disclosed an excess of advances in the list of wholesale quotations, and premiums on prompt shipments of certain commodities demonstrate that some needs are becoming urgent. Conspicuous among the favorable features is the decisive turn for the better in the automobile industry, where sales and output have increased substantially, and building operations of magnitude have continued. Despite labor troubles, the general outlook is of brighter promise, although not without elements of uncertainty. Doubts about the outcome of the crops are a cause for some hesitation, but present prospects appear to be mainly encouraging, and higher prices for farm products have enhanced the purchasing power in agricultural regions. Considerable irregularity in retail distribution has resulted from variable weather and strikes in some sections, yet consumption of goods, if still marked by conservatism and discrimination in buying, is of larger volume.

(Kansas City Star)

The Only Question Now Is Where and How to Float It.

Steel in the Stock Markets

THE flurry in steel stocks, due to the talk of mergers, was the outstanding event of the fortnight in the speculative markets. The announcement of the conclusion of an arrangement between the Bethlehem Steel Corporation and the Lackawanna Steel Co. was the signal for feverish buying of the securities of the independents, especially Lackawanna. After a day or two profit-taking set in.

The stock market as a whole has been sluggish and uncertain. The tone, in general, is reactionary, and there is said to be a considerable short interest. Still, competent and unbiased observers are not inclined to be pessimistic. F. Schneider, Jr., financial editor of the *New York Evening Post*, thinks that the condition of the market is neither surprising nor disturbing.

"Attempts to explain the condition on the basis of what is happening or is not happening at Genoa are gratuitous," Mr. Schneider says. "The market's behavior is quite consistent with its own technical position. After a winter of advances under professional auspices, the public, impressed by the improvement in the heavy industries, came in on a strong spring rise. A speculative position of considerable magnitude was built up. At the same time a large volume of capital issues were placed on the market. In addition, a number of unusual financial transactions produced a slight tightening in money rates. Under the circumstances nothing could be more natural than that this particular upward movement should reach a top and dwindle away."

Tax-Exempt Bonds in Demand

BONDS as well as stocks are acting in an uncertain manner. Recent heavy offering of new issues has taken the edge off the market, and consequently the volume of new financing

has dwindled. Investment houses are devoting their attention to getting rid of the remnants of old issues that they still have on their shelves.

The demand for tax-exempt bonds, however, has increased. Part of the inquiry, it is said, is coming from investors, both individuals and institutions, who are seeking this outlet for idle funds. Others are exchanging Victory notes and short-term Government securities for other tax-exempt issues of longer maturity.

In the new issues, therefore, the tax-exempt bonds predominate. One hundred million dollars of this class of security were brought out in the week ending May 12. The largest offering was a block of \$75,000,000 4½% Federal Land Bank bonds, maturing in 1942, which were brought out at par by a syndicate consisting of Alex. Brown & Sons, Harris Forbes & Co., Brown Bros. & Co., Lee, Higginson & Co., the National City Co., and the Guaranty Co. of New York. Other tax-exempt offerings ranged from a \$39,000 road improvement issue of the Village of Larchmont to a \$2,000,000 forest preserve loan of Cook County, Illinois. The largest industrial issue, a \$5,000,000 7½% first mortgage loan of the Francisco Sugar Co., was brought out by a syndicate headed by the Bankers' Trust Co.

Too Much Gold

AN interesting bit of financial statistics appeared in a recent Federal Reserve Board statement, which reported that the gold reserves have passed the \$3,000,000,000 mark. Apparently the flow of gold to this country has been only slightly checked. The gain in reserves since January 1 was slightly more than \$130,000,000, and for the past twelve months it was about \$642,000,000. The total in 1917 was \$1,000,000,000, and in August, 1918, it passed the \$2,000,000,000 mark.

A Twelve-Month Record of the New York Security Market, Continued on Opposite Page, Showing Economic and

In former years a condition such as this would have been hailed with joy. Today financiers are considering means of facilitating the flow of this gold back to other nations so as to improve the situation here.

"Some day much of this gold will again trek outward," says the *Boston News Bureau*. "It is explicitly regarded by Federal Reserve authorities as being to a large, if indeterminate, proportion held now in escrow."

"If the suggestions of some commentators are followed, that process will be accelerated by formal loans of much of this gold to other countries which sorely need it to re-establish their weakened currencies on a gold basis. By such loans we might obviate or minimize pressure to capture that needed gold from us through an invasion of commodities. First, however, such countries would have to adopt sundry fiscal reforms. The defining of these reforms has been—amid the political clamors—the well-done work of the commissions at Genoa."

Our Foreign Credits

WHEN Europe has carried out some of these fiscal reforms America may be ready to follow the advice of James A. Farrell, president of the United States Steel Corporation, offered at a speech before the National Foreign Trade Convention at Philadelphia. Mr. Farrell suggested that the billions of dollars of foreign indebtedness to the United States be transferred to the status of investment in foreign properties, preferably properties rendering public service. Such a readjustment would have a beneficial effect on our foreign trade and on the international exchange situation in general, Mr. Farrell said.

"We would then be building for ourselves for the future," he added, "and there need be no question then of wiping off these huge items of indebtedness which cast their sinister shadows over the international exchanges and which more directly influence them if payment is ever attempted."

One of the resolutions passed by the convention urged that America co-operate in world rehabilitation by reinvesting abroad at least the interest accruing on foreign loans and by the development of an American investment market for foreign securities.

Still After the Bucket Shops

THE bucket-shop agitation in the newspapers has subsided, but officials of the New York Stock Exchange are still at work on an elaborate program to protect the small investor. President Cromwell of the Exchange said in a speech at Philadelphia that when the present examination of financial reports submitted by member houses is completed there may be 100 fewer members doing business.

"The one enemy that the bucket shop really fears is the Stock Exchange," said Mr. Cromwell. "The only effective work done against the bucket shops has for many years been by the Stock Exchange. We are the last bulwark against the swindlers of the public. If political control is injected into the situation, such a condition as exists today in Montreal will exist in New York and spread throughout the country."

"In Montreal, in an incorporated exchange, working really under the old Napoleonic code, an attempt to discipline members for fraud is a farce. Members are fined and do not pay. Members take into partnerships people of bad reputation and the Exchange is helpless to prevent it."

"Only through a control which imposes ethical as well as legal restraint can the affairs of such an institution be safely and successfully guided. Regulations of the Stock Exchange are far in advance of the law in coping with the abuses outcropping from time to time as sharpers ply their practices."

Railroad Finances Looking Up

INTEREST in railroad securities for investment increases, in view of the improved showing of many roads for March, and the rather general feeling that the April figures will also be favorable. Railroads which depend largely upon coal traffic have, of course, suffered from the strike, but traffic in high-class merchandise, it is reported, has improved to a hopeful extent. The hopeful frame of mind in which the experts are waiting for the April figures is exemplified in the statement of Warren Lorimer, who says in the *Financial World*:

"Even the chronically pessimistic are now beginning to admit that their conclusion, doubtless influenced by propaganda from some quarter, has been all wrong and that April will be more

(Turn to page 1040)

Political Developments Accompanying the Continuous Rise Since August. - (Brookmire Economic Service).

Keep Power Plant Records

THE importance of power plant records is often underestimated by managers, says C. C. Hermann in *Industrial Management*. A system of power plant records provides (1) Costs which may be compared and which indicate the degree of economy in the operation of the plant, and (2) A means of checking up the various units to eliminate wastes and intelligently direct the activities of the plant.

The essential records pertaining to a power plant are of two types—permanent statistics and operating records. Permanent statistics include all data used for repairs, improvements or appraisals. Drawings and specifications should accompany these records. Operating records include (1) Yearly statistical records, (2) Monthly statistical records, (3) Daily power plant records, (4) Material requisitions, and (5) Labor reports or time cards. Monthly costs of operating the plant should be pro-rated over the various mechanical units and not given as a lump sum. All labor expended should be charged to the production of power, to improvements or to repairs. Materials should be charged off to an asset in the general stores account.

Who Does the Work?

A METHOD of charting the relationships between operations and the personnel which perform them is described by Boyd Fisher in *Management Engineering*. The chart consists of intersecting horizontal and vertical columns. The names of all persons concerned in the completion of a task are shown across the top of the chart, one to each vertical column. The different steps in the execution of the work are indicated down the left-hand side of the chart. At the intersection of each horizontal column with the appropriate vertical column of the person concerned a symbol is placed indicating what share of the operation is done by that individual. Symbols are assigned for such functions as "furnished by," "studied by," "information gathered by," "originates with" and "goes to." By glancing down the column under his name a clerk or executive can readily determine every operation for which he is responsible and, in addition, the nature of the responsibility.

The customary Routine of Operations chart, of which Mr. Fisher's is a modification, goes a step further by indicating not only the relationship between operations and those who perform them, but also the sequence of

operations for a particular unit, either clerical or manufacturing. This is accomplished by listing the steps in logical order down the left-hand side and placing the symbols under the vertical headings in circles. The circles are joined in order by straight lines and the path of an order, piece of material, or other unit is clearly shown. This is particularly valuable in the study and standardization of routine operations as cut-backs and repeated travel are indicated and the standard routine of operation can be designed to eliminate waste. With this added feature the chart becomes in reality a statement of the routine and a flow of work diagram combined.

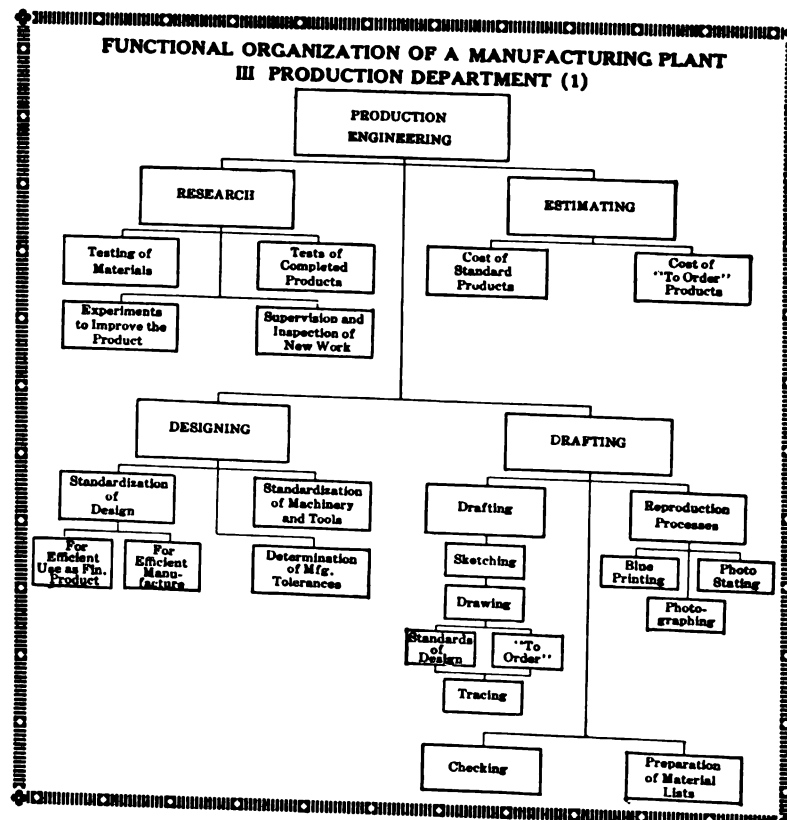

Distribution Waste

SUGGESTIONS for eliminating waste given by 100% Management include: A resale department for surplus and obsolete material, a salvage department for defective material that may be re-used, inventory reductions, elimination of needless office records, and reduction of selling costs by revision of mailing lists, planning of salesmen's time and choice of effective advertising mediums.

Keeping the Promise

A PROMISE system that saved 20 percent of the operations formerly necessary to handle an order was installed by E. L. Sherwood in a plant manufacturing a large number of "to order" articles. All orders are given a promise date by the planning department, which notifies the purchasing and sales departments of the factory promise date. If the promise to the customer does not agree with the factory date an adjustment can be made before the customer complains of

delayed delivery. Scheduling is done four weeks in advance up to 85 percent of the capacity of each department based on a normal working force. The control sheet shows work ahead and hours of labor required, the latter being segregated according to operations. If the work schedule for the ensuing four weeks shows an unusually large volume of work, additional help or material can be procured with ample time for careful selection. On the other hand, if the schedule shows little work ahead, the factory force can be reduced without interfering with the progress of the work. The factory order is enclosed in a strong, transparent cloth envelope and attached to every piece in process. With the factory order is also attached a tag with large numerals designating the

Functions of a Typical Industrial Plant

This chart is third in a series based to a large extent on lectures given at the Bureau of Personal Administration by Warren D. Bruner

day of completion. All through the various operations in the factory this number serves as a priority indication for the particular order and affords a ready means for foremen and inspectors to detect variations from schedule.

Fixing Salesman's Quota

A SALES plan that has produced exceptional results is explained by George F. Pierrot in *Business*. At the beginning of each month every salesman sets a mark for his own sales for the month. From these estimates the general manager makes up a blackboard sales chart. This chart lists the salesmen in the order of volume of business each obtained during the preceding month. Opposite each man's name are tabulated squares, one for each product which the company sells. Each square is divided diagonally and in the upper half the salesman's estimate is shown. The lower half is the record of what he actually sells. Totals for each week are recorded in four colors of chalk. A star identifies the leader in volume for the month to date and a triangle the leader for each week. An ambitious salesman sets a large quota for himself and then feels compelled to equal or surpass his estimate. The management itself sets no mark but has a fair minimum in mind which the average salesman is expected to meet.

Lay Out the Work

THE first step in applying scientific principles to cost finding is to survey conditions and make a definite plan of procedure. Robert S. Denham, writing in *Industrial Management*, outlines the facts which the cost engineer or accountant must ascertain preparatory to actual cost finding. These factors are: (1) The range of the product; (2) The materials of which it is composed; (3) The processes by which the materials are formed into the product; (4) The classifications of product which require routing through different groups of processes; (5) What means are at present operative for the storage, recording and conservation of materials and parts; (6) What are the requirements, and what means are operative for storage, recording, sale and delivery of the finished product; (7) To what extent expenses are generalized, individualized, or classified, in the accounting system used; (8) What plan, if any, exists in the organization of the commercial and factory personnel; (9) What methods are in operation for the collection of data intended for use in the determination of cost of production.

Foremanship Qualifications

ANSWERING the query, "What determines successful foremanship?" Edward S. Cowdick, writing in *Management Engineering* deems the following qualities necessary: (1) Leadership, (2) Fairness, (3) Willingness to work, (4) Self-control, (5) Ability to teach, (6) Knowledge of human nature, and (7) Influence for good citizenship. Foreman qualified on this basis can be secured only by selecting suitable raw material and properly developing it through foremen's training courses.

Watch Stock Records

STOCK and cost records are the weakest links in the office systems of many concerns. A. J. Carson in *Business* outlines a practical stock system and its application to the control of the business. The fundamental law governing the number of times that an article must be turned annually at a given rate of profit is based on the annual stock turn and average percentage of gross profit as shown by past records. From this basis a table can be devised showing: (1) The least number of times per annum that articles must be turned at given percentages of gross profits in order to conform to the general average desired; (2) The percentage of expense applying against this gross profit at the annual rate of stock-turn; and (3) The net profit, provided the number of stock-turns specified is maintained.

The stock record shows, in addition to the quantities of goods bought and sold, the values of those quantities. Costs are entered from the invoices and represent the total laid-down cost of the costs on the floor of the warehouse. The sales quantities and values are taken from the sales sheets. The value of the inventory on hand subtracted from the total cost gives the cost of sales, and the difference between the total sales value and sales cost is gross profit. The percentage of gross profit is figured by dividing gross profit by total sales. This percentage determines the classification of the article and its number of stock-turns a year.

The stock record also provides for a standardized designation of each article—unit, size, stock number, etc., maximum and minimum quantities to be carried, average quantities to be sold each month and the "price guarantee." Stock governed by price guarantees must be moved before that date. The words "short," "ordered," "acknowledged," "shipped" and "long" are shown on the stock card and metal signal tabs used to give the condition of the stock at a glance.

The advantages of the system are: (1) Gross profit on each article is shown, (2) Rate of stock-turn is shown and can be adjusted on basis of profit, (3) Percentage of expense on each article can be determined, and (4) Net profit is indicated.

Standardization Simplified

STANDARDIZING the work of standardization by the use of fundamental data common to all plants in the same industry is advocated by W. O. Lichtner in *Management Engineering*. Standardization requires the analysis of each operation and the building up of the elements studied into a practical, efficient standard of operation. The analysis of operations and establishment of unit times for performing these operations constitute the fundamental data which should be common knowledge to all plants. As a rule these data are not available, either because they have been kept secret or because the varying methods of analyzing operations have given results which are not comparable. Data of this nature should be compiled and put in handbooks for general use, correct allowance being made for such factors as (a) Nature of the product, (b) Skill of employees, (c) Machinery and equipment, (d) Methods, (e) Degree of planning and control, (f) Supervision, and (g) Special conditions. The use of such fundamental data by plant executives generally will result in the elimination of waste effort in developing standards, a basis for agreement between Capital, Labor and Public and will provide a means for determining labor and equipment requirements for manufacturing operations.

Handling Scrap

A SOLUTION of the scrap problem is put forward by the *National Association of Cost Accountants* in a recent bulletin which outlines the following course of action: (1) Prevent scrap at the source by study and elimination of causes and by reclamation. (2) Handle scrap efficiently by segregation at the point of origin, systematic collection and transportation and preparation for profitable disposal. (3) Dispose of scrap for the best returns by maximum consumption of scrap within the factory, finding the most profitable markets and meeting the demands of consumers. (4) Account for scrap correctly by getting accurate costs on the loss and salvage value, crediting scrap to material or individual lines of product and maintaining sufficient records for the compilation of reports.

The results claimed for this method of handling the scrap problem are: less scrap due to conservation of raw materials, lower costs through economies effected, less expense because the quantity of scrap handled is reduced, higher prices because the scrap is clean and well separated, and correct accounts whereby the material costs can be properly credited.

Two Important Decisions

TWO important decisions have been made recently which will have a direct effect on labor conditions. The first is the recent ruling of the Supreme Court in regard to the constitutionality of the child labor legislation. This decision holds unconstitutional legislation penalizing manufacturers who ship goods, made with child labor, from one State to another, under interstate commerce regulations. The ruling has caused a bitter feeling among labor leaders, and it is possible that it will be made a political issue by some of the unions interested.

The second decision was given by the Railroad Labor Board and forbids "farming out of shop repair work by the railroads to outsiders." This decision, which is the first of a series to be handed down on disputes on "farming out" railroad labor, will govern the decisions in thirty-six similar cases now before the board, involving seventeen railroads. Under this decision thousands of former railroad employees now working for contractors at wages lower than the Labor Board scale are brought back into the labor board's jurisdiction. Rules varying from those laid down by the board are likewise, in effect, declared illegal and the contracts employed are likewise to be governed by the working rules promulgated by the board. The board declared that if a railroad company could remove its employees from the jurisdiction of the board, as was attempted in the Indiana Harbor Belt case, "then the entire Transportation Act can be nullified." It is estimated that the decision will affect more than one hundred and fifty thousand shopmen now in the employ of contractors handling railroad work.

It is probable that this ruling will prevent the threatened strike of the railroad shopmen, numbering some 600,000.

Building Trades Disputes

THE recent settlement of the building trades dispute in Cleveland is likely to be followed by another in Boston. The building trades struggle in Chicago has turned into a bitter contest, culminating in reported acts of violence on the part of union sympathizers and the wholesale arrest of labor leaders. The Chicago trouble is a flareback from the Landis wage awards, which many of the unions have never accepted in principle, and further difficulties are anticipated in the Chicago district before the matter is settled. At the present time many prominent labor leaders are in jail following the murder of a policeman, incendiary fires and threats of violence.

Coal Strike Deadlock

THE coal strike seems no nearer a settlement. On April 1st more than 514,000 anthracite and bituminous miners stopped working. At the end of the second week of the strike 117,000 out of a force of 238,000 non-union miners had joined hands with the strikers, according to the union. These figures are held to be much above the actual number out, according to railroad executives. In the bituminous field the situation is becoming more serious every day, as accumulated stocks of coal are being reduced. Government intervention is expected to come at any time, according to many newspaper editors.

Labor Only Bar to Prosperity

ACCORDING to the last monthly review of general business made by the Federal Reserve Board, labor troubles form the only cloud on the industrial horizon. "Due to the widespread mill strikes there has been a reduction in mill activity in New England (textile) mill districts. Leaving out

Railways Make Better Showing in 1922

The accompanying chart shows weekly car loadings, shortage or surplus of freight cars, and earnings of Class I roads on their valuation by the Interstate Commerce Commission under the Transportation Act of 1920. The shortage of cars that prevailed number of idle cars in 1921 reflect the industrial depression of that year. The pronounced gain in car loadings and corresponding decline in number of idle cars during first three months of 1922 were due chiefly to heavy shipments of coal in anticipation of the miners' strike in union fields, which began on April 1. The effects of the strike on railway traffic are shown by these so far as earnings (percentage on official valuation) are concerned, since the new Transportation Act went into effect. With though they have fallen short of the 6 per cent. contemplated in the Transportation Act. The best showing so far was for March, when earnings amounted to 5.8 per cent. on official valuation.—(New York Evening Post.)

Germany Builds Railroad Locomotives for Russia

One of the new locomotives manufactured for the Russian Soviet Government at the Essen Works of the "Rheinmetall." The engine can burn wood for fuel when coal is not available. Note the emblem of the Soviet Government over the number of the engine.—(*International*.)

voluntary unemployment, the result of strikes, a decided increase in the number of employees is noted. There has been a 2½ percent increase during the month in the number of workers employed by firms reporting to the United States Employment Service. The improvement noted will, however, be offset to some extent by the widespread unemployment in the coal mining regions as well as in the New England textile centres. . . . But for labor disputes industrial activities would be pronounced definitely good with promise of improvement in those directions in which, heretofore, prospects have been unsatisfactory.

Resistance to Wage Cuts

ACCORDING to the *Philadelphia North American*, through all the industries of the United States there seems to be a general tendency by labor to stiffen resistance to wage cuts and to support attempts to maintain present working conditions. Especially is this true in the sections where skilled workmen see in the present business revival a relief from the unemployment that has affected them. Among unskilled workers, however, there is still a large surplus of unemployment and no immediate signs of the elimination of this surplus.

Regulation to End Abuse

THE following regulatory measures have been suggested by Samuel Untermyer, counsel of the Lockwood Committee, to end the abuses of organized labor: (1) Submission by each union of its Constitution and By-Laws for approval to a State Commission and granting to each a license, if an unincorporated association, and if they contain nothing contrary to public policy. (2) Right of a member of a union to review any terms of his union that he believes to be unjust to him. (3) Right of any person feeling aggrieved by the action of a union to a like review. (4) Right of any complainant having a grievance against the rules and practices of a union to have

such abuses abated, being in this respect somewhat analagous to present authority of the Federal Trade Commission to prevent unfair competition among corporations engaged in interstate commerce. (5) Privilege of either party to a controversy before the commission to appeal to the courts from its decision.

Reported Earnings

THE United States Department of Labor reports average monthly earnings in a number of industries as follows:

Industry	April 1922	March 1922
Steel	\$88	\$84
Automobile	112	108
Cigar making	68	68
Men's clothing	108	108
Car repairing	116	116
Cotton manufacturing	64	68
Paper making industry.....	92	96

Industrial Revival Is Better Than Anticipated

THE condition of business shows little change. Steel works still operate at rates approximating the best attained in something over a year. Automobile makers are enjoying an unexpectedly good demand. The building boom retains its vigor. There may be signs that the present burst in steel buying has reached its peak; much of the present business was taken at low prices and production costs have risen as a result of the coal strike. Also as a consequence, railway car loadings are falling, while the strike itself promises to be prolonged. The approach of summer usually brings a general slackening. Nevertheless, it is clear that this year's industrial revival has been distinctly better than anticipated, and that barring misfortunes, such as a rapid marking-up of prices or a top-heavy tariff, progress should be continued.

(*New York Evening Post*)

Copy Suggestions from Buyers

ALTHOUGH it would seem that the price argument would be particularly apt when selling a new idea like mutual insurance, says Roy Dickinson in *Printers' Ink Monthly*, the Liberty Mutual Insurance Company of Boston, discovered that price was not the big selling argument. An advertising campaign, emphasizing the reduction in price failed to pull. So the company decided to ask its customers what was wrong with the sales appeal. Automobile insurance was selected for the test. Six advertisements were prepared, similar in size, style, and general arrangement, but the illustration and copy were different in each case. Copies ten and twelve inches in size were furnished the investigators for the tests among car owners.

Many interesting discoveries were made by going to this source of information. Perhaps the most important fact that was brought out was that all of the advertisements showing a wreck received a higher rating than those which featured security or price or some other appeal—proving that the association of two ideas so closely related as an automobile wreck and insurance will produce interest in the consumer's mind.

It was found that the most frequent comments made about the advertisements that did not win were "Takes too long to understand," or "Takes too long to read it," "Hard to tell what it is all about."

"Tell Us Something! Hang the Length!"

IN the opinion of Robert H. Isbell, in *Printers' Ink*, readers like long advertisements if they contain vital matter to the end. He believes that the signs of a return to longer copy are high signs of real betterment, and that there is room now and always has been room for painstaking, practical copy that tells the business story with thoroughness and naturalness. The lengthy advertisement, if it has something to say to justify its length and says it well, sticks in the memory. Whether it is read or not, the fact that an advertiser has so much that he considers worth telling gives the impression that he has an article worth telling about.

Magazine Values Analyzed

AT a recent meeting of the Poor Richard's Club in Philadelphia, G. Lynn Summer, advertising manager of the International Correspondence Schools, analyzed magazine advertising values in this way:

Taking the "attention value" of a full-page magazine advertisement as 100 percent, a quarter page would rate 47 percent; half-page, 71 percent; full page in colors, 113 percent; double spread in black and white, 114 percent; back cover, 283 percent; pages one and two, 231 percent; right page, 5 percent more than left; upper half, 25 percent more than lower half. Although newspaper advertising may bring more immediate results, magazine advertising holds attention during the longest period.

How to Sell an Advertising Campaign

IN selling advertising campaigns to Boards of Directors, the needs of the prospect must be kept definitely in mind and in the foreground throughout the entire procedure, says William H. Rankin, in *Advertising and Selling*.

It is in terms of markets, not newspapers or magazines, that the most logical presentation of a campaign can be made. It is in terms of cost per reader of copy, not cost per line of copy, that the advertising campaign may most readily and

directly be shown a paying investment. The fundamental questions in the minds of directors are always: Where are the prospects for our goods? How many prospects can we reach? How many can we expect to sell? Although parts of the answers to these questions lie in the details of space used in copy and art work appeal, the fundamental and first necessity is an analysis of the advertiser's market.

Charts or blue prints should be presented visualizing what the advertising campaign is expected to accomplish, coupled with what the advertiser actually gets for each dollar spent. The charts presented at the conference should do more than represent the mere plan of advertising. They should build up a complete selling policy which will visualize not only to the directors, but to the sales force, the opportunities and profits which will result from co-operation in all departments of the advertiser's or manufacturer's organization.

Train Dispatching System for Mail Orders

"WHERE goods are in stock, if more than twelve working hours have been consumed in filling this order, you are entitled to a forfeit of one dollar. Our working hours are from 8 A. M. to 12 M. and from 1 to 5.30 P. M. daily, except Saturday, on which day we close at 12 o'clock noon."

This statement defines one of the practices by which Selz, Schwab & Company have succeeded in injecting an unusually human touch into shoe merchandising by mail.

According to Lyman Anson in *Printers' Ink Monthly*, the plan originated several years ago at a time when it was somewhat of a novelty for railroads to say, in substance, to prospective travelers: "Look here, maybe you think we can't get you there on time. But we can. We're not fooling. To prove it, we'll give you a dollar for every hour we're late."

After reading these railroad advertisements the president of Selz, Schwab & Company came to the conclusion that the time element idea might make the sporting appeal to his mail-order customers that it made to patrons of the railroad. He believed that if he challenged them to watch whether or not he could get their orders in a given time—made it a sort of game in which he was racing against time with a few thousand mail-order customers holding their watches on him—they would soon be taking as much interest in the shoe "game" as he himself had taken in the challenge of the railroad. That was the psychology of the new plan of railroading orders through the Selz organization on a train dispatcher's schedule.

When an order comes in by mail the first thing that happens to it is for the clerk to attach a record slip of the proper day. The space on the slip, headed "Received," then has stamped on it the exact time to the minute at which the order actually arrived. A few moments later the order with time slip attached reaches the "entry" desk, where it receives another time stamp. From there it passes through the several departments necessary to get out the order. The next imprint from a time clock comes when the order arrives at the packing room, after which it is turned over to the last of the four dispatch stations—the shipping and billing departments, where it gets a final punch, and is on its way to the customer. At this last station the time record slip becomes detached from the original order from the time it is received until the goods are forwarded.

As a result of the adoption of the plan, it is said that credit relations have been greatly improved, and collection difficulties cut in half because the customer finds it easier to meet smaller, though more frequent obligations.

EXPORT • IMPORT

Foreign Trade Convention

AT the ninth National Foreign Trade Convention, held in Philadelphia May 10 to 12, some two thousand delegates from all sections of the United States and a number of foreign countries found themselves substantially in agreement as to the causes of the present world-wide depression in trade. All the remedies suggested recognize as fundamental the need for a return to "normal world trade conditions." The speakers generally recognized the economic interdependence of nations, and stressed the need for extending aid to Europe. A summary of the leading addresses follows:

Importance of the Fifteen Percent

THE interdependence of nations and the necessity of the United States maintaining its foreign trade was the keynote of the address of James S. Alexander, president of the National Bank of Commerce. Although the foreign trade of the United States is but 10 or 15% of its total trade, it is a highly important part. The foreign trade of the United States is essential if the people of the United States are to maintain their present high standards of living, since the maintenance of this standard is dependent upon an ever-expanding market for our surplus manufactures. The welfare of other nations is then so closely interwoven with that of the United States that we must consider the trade of these other nations in considering our own. Once the close interrelation between the welfare of one country with that of other countries is clearly recognized, many of the present doubts and difficulties in our international trade policies will be swept away.

Insure at Home

VITAL points in marine insurance and a résumé of the relations between the insurer and the insured were the subject of a paper read by W. H. La Boyteaux. The selection of the insurance company, with regard both to the financial standing of the company and its morale—the attitude of its officers and agents regarding settlement of claims—is most important. The marine insurer doing business in the United States is regarded as the equal of the foreign insurers in every way, while insurance laws and practices on the Continent are so different from those to which American insurers are accustomed that Continental insurance contracts may be of little value.

Advertising Abroad

IN the discussion of practical selling plans, emphasis was laid on the study of markets and the use of well-directed advertising to promote sales and decrease selling costs. Because foreign advertising involves much greater extensions of time than does domestic advertising before results can be shown, it is necessary for the foreign advertiser to formulate his plans with great care and set up an appropriation for a year at a

time at least. The advertising man must be familiar with the physical aspects of the country, its government, political, economic and financial conditions, general standards of living, and the like, in order to select his appeal.

Transferring the Foreign Debt

IN one of the closing speeches of the convention, James A. Farrell, president of the United States Steel Corporation, and chairman of the National Foreign Trade Council, recommended the transference of the foreign indebtedness to the United States to the status of investments or actual ownership in property abroad. There would then be no question of wiping off these huge items of indebtedness which now cast their shadows over international exchange and which must still more directly influence the exchanges when and if payment is ever attempted.

Resolutions Adopted

THE resolutions adopted, which stand as the declaration of the council's policy, urge America to co-operate in world rehabilitation by extending credit, including long-term credit, to foreign customers; by a tariff policy "which will make it possible and profitable for other countries to sell to us in order that they may buy from us," by reinvesting abroad at least the interest accruing on foreign loans, and by the development of an American investment market for foreign securities.

International Normalcy

FRED I. KENT, of the Bankers Trust Company, summed up the factors of prime importance in the return of trade and commerce throughout the world:

Co-operation with Russia along lines aimed to reduce the menace of the Red Army and the vicious propaganda of the present government.

Quick settlement of the German reparations.

Cancellation after agreements as to co-operation of some percentage of the Inter-Allied loans that can fairly be estimated to represent a direct and legitimate war charge to the nations taking part in the cancellation.

Reduction of Government waste.

Stoppage of inflation caused by the issuance of new currency and increase in floating loans.

Removal of trade barriers by means of special commercial agreements and treaties between nations.

Greater co-operation between capital and labor and a better world morale working toward elimination of class and national hatreds.

Status of Foreign Trade

IN discussing measures for increasing our foreign trade, it is well to keep in mind rather the pre-war status of this commerce, and accept the tremendous boom which took place during the war as abnormal, however profitable it was at the

A Pretty Big Boy to Get Panicky

AUTOMOTIVE

Trucks Gaining More than Passenger Cars

ACCORDING to statistics recently compiled by the United States Bureau of Public Roads, the gain in commercial vehicles is progressing at a rate about twice as fast as that of passenger automobiles. While the total of 10,465,995 vehicles for 1921 shows an increase of about 1,250,000 over the 1920 figures, the rate of increase has fallen off, says *Engineering News-Record*. The total registration in 1921 was about 13.6% greater than that of the previous year, as com-

pared with a 22% increase for 1920 as against 1919. The same relationship, however, does not hold for the commercial-vehicle classification, where a 22.7% increase is shown by the year 1921 as compared with 1920 (last year there were recorded 1,033,151 commercial vehicles, including motor trucks, buses and taxicabs, as against 841,690 in 1920, a gain of 191,461). This 22.7% increase in commercial-vehicle registration compares with a 12.7% increase in passenger cars.

More Definite Planning Needed in Market Study. Many car manufacturers seeking to broaden their markets start an analysis of the possible markets, but do not seem to know just exactly what they are driving at, and after considerable expenditure of time and money drop it. Then they claim their markets cannot be analyzed in the ordinary way. Author points out that any market analysis must have a definite objective, and must proceed toward it in regular steps. Another point made is that when data is gathered and is available, it should be considered by all departments, especially production, financing and administrative planning. To produce maximum results for the time and effort expended, all the information must be correlated and the relation between the various units made clear. NORMAN G. SHIDLE, *Automotive Industries*, 3-30-22, 1960 w. MAH.

Building and Servicing Truck Bodies. Opening sentence is, "Service in its broadest sense must cover every phase of the marketing and operation of motors and trucks." With this basic thought, authors proceed to develop general plans followed by chassis builders in securing body equipment. Advantages and disadvantages are set forth. Other topics are: standardization of body parts, and what it would mean to all concerned; need well-proportioned design, neither too light, leaning toward carriage work, nor too heavy, leaning toward heavy trucks; the dealer attitude toward bodies as separate units; possibilities for business through separate sales (to dealers) of chassis and body, advantages of sectional body types, and similar topics. C. M. MANLY and C. B. VEAL, *Power Wagon*, 4-22, 10,000 w. MAH.

Function of Vibrating Voltage Regulator. Describes purpose and form of vibrating type of regulator, as well as its operation. Also describes the tapering charge, double functions, causes of earlier failures, condenser in shunt to vibrator, temperature compensation and regulating the resistance. Diagrams and oscillograms are presented and discussed. W. P. LOUDON, *Automotive Industries*, 4-13-22, 2950 w. MAH.

Design of Laminated Automobile Suspension Springs. This is final installment. In this part author takes up such phases of general subject as grading, stiffness, materials, tests of materials

Classification by Capacities of Total Number of Trucks in Use.—(*Automotive Industries*).

and springs, blade ends, eyes, center bolts, clips, spears, proportions, deflections under load, maximum test loads, standard tests, accuracy of dimensions, fixing, formula for semi-elliptic forms, investigation of representative front and rears from a random lot, analysis of dimensions checked at random, etc. A. A. REMINGTON, *Automotive Industries*, 4-13-22, 7300 w. MAH.

Relation Between Recommendations of Three Oil Companies for Automotive Lubrication and the Actual Sales of the Various Grades.—(*Engineering World*).

Assembling 150 Engines a Day. An output of this tremendous size, such as could be reached only in six or seven plants in the whole world, necessitates special methods and much special apparatus. Author describes both, based on new Jewett plant of the Paige Motor Car Co. It is largely a picture story, but in the rather brief text the methods of machining cylinder blocks, flywheel housings, pistons, crankshaft and connecting rod sub-assembly parts, and timing gears are outlined and the assembling described in more detail. The preliminary work is mentioned, and the testing covered quite thoroughly. J. EDWARD SCHIPPER, *Automotive Industries*, 4-13-22, 2100 w. MAH.

Commercial Aviation Developments in Europe. Commercial development of air traffic in Rumania and other countries of Southeastern Europe. As France, England, Belgium, Italy and Germany have been covered in previous parts, and developments in Scandinavian countries and Russia have been practically nil, this installment concludes Europe. As for Rumania, the Bukarest-Paris-Constantinople line is about to be placed in regular operation. A number of flights have been made, but not on regular schedule. Trip from Paris to Bukarest takes approximately 35 hours. Other details. W. KNIGHT, *Aerial Age Weekly*, 4-17-22, 2300 w. MAH.

Pros and Cons of Truck Rear Axle Types. Author lays down the five types of rear axles now in use for motor trucks, and then proceeds to discuss the advantages and disadvantages of each. In this discussion, many technical points are stressed, with considerable mathematics. The author draws no conclusion beyond proving that a full floating axle shaft can be made lighter and cheaper, and still have a higher factor of safety than the shaft of a semi-floating axle. ETHELBERT FAVARY, *Automotive Industries*, 3-30-22, 6600 w. MAH.

Alcohol as Fuel on Exported Vehicles. In many countries no gasoline or similar light fuel is available, or, if available, is of such high price as to make its use almost impossible. This is particularly true of many South and Central American countries. Most, if not all, of these have alcohol of fair quality available. Author reviews advantages and disadvantages of its use, changes which should be made in cars of trucks destined for such

Baby Tractor to the Fore(d)

Henry Ford's "mechanical mule"—the Fordson tractor—was one of the most interesting sights at the recent tractor show at Long Island City, N. Y. The flivver tractor, said to be a bear for work, is here seen pulling a ditcher.—(Underwood & Underwood)

countries. From the latter, his chief points are higher compression, use of more heat of the fuel before vaporization and during it, larger fuel jets, protection or provision against its corrosive action. HERBERT CHASE, *Automotive Industries*, 4-6-22, 3400 w. MAH.

Sperry Flight Indicator. This is an instrument built for use in fog, in clouds, and combines the features of the turn indicator and inclinometer. The instrument is a small gyroscope, actuated by suction from the air stream of the propeller, its action depending on the well-known laws of gyroscope precession, that any rotary motion transmitted to a gyroscope (except about its own axis) causes it to move at right angles to the direction of the applied motion. This is called precession. The article gives all this as well as details of the construction and use of the instrument. *Aviation*, 4-3-22, 2200 w. MAH.

Tooling Equipment for Automobile Hubs and Pistons. This is one of *Machinery's* monthly series on the method of tooling up the machine, usually an automatic or semi-automatic turret lathe, for some more or less well-known part, in general automobile parts, gears or something usual. This installment takes up the work on the Fay automatic lathe, and deals with the set-ups for machining ball race seats in automobile front hubs, and other operations on the hubs, also all operations of rear hubs, tooling for stamped hub flanges, for aluminum pistons, and for cast-iron pistons of different design. RALPH E. FLANDERS, *Machinery*, 4-22, 2500 w. MAH.

Aeronautical Charts. Discussion of aviator's need for proper charts, best forms, most desirable scales, subdivisions, markers, frontiers, how maps are used, etc. STORY B. LADD, *Aerial Age Weekly*, 4-17-22, 3900 w. MAH.

Railcars Must Combine Automotive and Railroad Practice. The manager of the recently established railroad division of one of the larger motor truck firms points out that the most desirable features of both forms of construction must be incorporated in railcars to produce successful, economical, efficient operation over steel rails. He describes

the gradual progress of the gasoline-driven railroad car, and concludes with a thorough description of one of the latest automotive units. This has a passenger capacity of 46 passengers, 70 sq. ft. of baggage space, yet weighs but 26,000 lbs., or approximately one-third of the weight of the early railcars of slightly greater capacity. It is powered with a 60-hp. engine, against a 200-hp. unit in the earlier cars, thus making for greater economy of operation. Other data interesting to traction executives. CHARLES GUERNSEY, *Electric Railway Traction*, 4-22-22, 1300 w. MAH.

Gasoline Railcar Operated at 40 Cents a Mile. The Lewisburg, Milton & Watson town Passenger Railway has put this new gasoline unit into service between Montandon and Mifflinburg, 10.9 miles. It is a Mack A C chassis with a wheelbase of 22 ft., and a Brill body seating 35 in the passenger compartment and 5 in the baggage compartment. For February and March, operating figures show a cost of 40.23 cents average, March being much lower than February. Depreciation is figured on a basis of 8 years and

200,000 miles. Data on operation, schedule, force, traffic, etc., are given. *Electric Railway Jour.*, 4-22-22, 550 w. MAH.

Relation of Carburetion to Fuel Economy. Second part of a long article on this subject. In this section the author considers vaporization from a theoretical and practical standpoint. Some of the points taken up are: Deflection of the charge by the throttle valve, metering, distribution of the charge, rate of vaporization and how it may be accelerated, need for heat and its application, hot-spot manifolds, relation of vaporization and distribution to economy, and other points. He concludes that proper operation of the entire system depends on complete and instantaneous combustion of the fuel. J. N. GOLTEN, *Automotive Industries*, 3-30-22, 3650 w. MAH.

Theory of the Screw Propeller. Theoretical treatment of the theory of aerofoils is difficult because of our lack of knowledge of the mutual action of propeller and airplane, and the handling of the problem is made difficult by the limited ability of geometrical presentation, this being limited because of the spiral action in space. The mathematical treatment is rendered still more difficult by the problems connected with propeller symmetry. All this the author goes into in considerable detail, without, however, getting into the actual mathematics of the case. An important translation from the German technical press for the designer. A. BETZ (Göttingen), *Aerial Age Weekly*, 4-10-22, 3700 w. MAH.

Making Auto Parts Toe the Mark

If all inventions for automobiles were applied you wouldn't be able to see the automobile. The Underwriters' Laboratories in Chicago uses this vibration table in testing proposed improvements which would be subject to vibration in actual use.—(Underwood & Underwood)

BUILDING-CONSTRUCTION

Building Activity on the Up-Grade

THAT recent predictions in regard to an upward turn of building activity are being justified is indicated by the accompanying chart. The curve of stabilization represents the building cost line at which investors in this field may be expected to build without too great shrinkage in the reproduction value or income value of new buildings. The index line representing the actual cost of building entered the zone of stabilization in the fall of 1921. According to *Architectural Forum*, if this cost passes out of this zone building volume will decrease materially.

The course of this stabilization curve is based on an analysis

of the time involved in return to normal conditions after the Civil War and the War of 1812; the effect of economic control exercised by the Federal Reserve Bank in accelerating this return after the recent war; and an estimate of the probable normal increase in building cost.

The various factors that control activity in the building field indicate continued improvement. Money available for new construction is increasing, while the cost of financing appears to be decreasing. It is also believed that producers of material and others who control the factors of building cost will not make an attempt to increase prices.

Changes in Construction Costs and Effect Upon New Volume and Investment

Present-Day Ventilating Practice. Comments on conditions now sought through installation and operation of properly designed air-supply systems. Covers: humidity standard, importance of reducing dust, effect of odors, fallacy of low air velocity and uniform temperature, Palmer arraignment, outdoor conditions, variations in dust count, influence of high first cost and operating cost, tests with recirculated air, suggested standards for supplying washed recirculated air, suggested standards when using fresh air only. Very comprehensive article. NELSON S. THOMPSON, *Heating & Ventilating Mag.*, 4-22, 7000 w. CS.

Acoustics! Whose Business Is It? Lack of regard for basic essentials renders many public buildings useless, and con-

ditions for hearing are ignored in specifications. Architects should consult experts, as problems of acoustics can be handled with scientific certainty. M. C. ROSENBLATT, *Construction Economics Edition, Amer. Contractor*, 4-15-22, 2000 w. CS.

Heat Balance and Steam Distribution in Large Service Plant. Tells how steam, hot water and power are charged to different departments in large building supplied from isolated power plant. S. D. KUTNER, *Power*, 2-28-22, 4800 w. CS.

Effect of Soil Moisture on Highway Design. Covers: capillary flow, capillary saturation, capillary moisture and gravitational, supporting power of sub-grade, thick pavements. J. L. HARRISON, *Municipal & County Engineering*, 4-22, 2500 w. CS.

Origins of Fires. Description of recent fire which partially gutted the Burlington Office Building in Chicago with small injury to the structural framework. Statistics are also presented of fires in 1,254,192 buildings in the United States with types of construction, frame, brick, stone, etc. Fewer fires in frame buildings than in all others, although three-fourths of all buildings reported were frame. *American Architect*, 4-12-22, 1000 w. EMCC.

Training for the Apprentice. Unions and employers both responsible for technical training of apprentice. Untrained man works harder and accomplishes less. Viewpoint of A. F. of L. leader. HUGH FRAYNE, *Construction Economics Edition, Amer. Contractor*, 4-15-22, 3500 w. CS.

Study of Architectural Design. All study of proportions regulated by those of interiors. Natural order of study is first to make tentative disposition of rooms and spaces required—which is the plan; then to determine necessary heights of stories, of windows and of roofs—which is the section. Should be remembered that plan is only horizontal section, section is vertical plan, and that these two have as their resultant a facade. Each of these studies—plan, section, elevation—is the complement of the others; they cannot be treated as successive phases of study. Usual error is to make motives too small in scale, to crowd too many into a few feet. Also a mistake to go to opposite extreme; extravagant proportions do not give grandeur in composition. Grandeur of aspect obtained by simplicity, unity, number of elements. JOHN F. HARBESON, *Pencil Points*, 3-22, 1500 w. (Eighth in series.) HHH.

Standard Roadbed Cross Sections. First instalment included the Minneapolis, St. Paul, Syracuse, Winnipeg, Omaha and Toledo cross-sections, and this one takes up those of Youngstown, Milwaukee, Philadelphia and Cincinnati. Details of the rails, concrete or other foundation, drains or other piping to be considered, ties, rail chairs and other technical points are described and standard sections for single and double track illustrated. Method of procedure is given in some cases, and, if available, cost figures also. *Electric Traction*, 4-22, 1400 w. MAH.

Thrust of Skew Barrel Arch Measured on Laboratory Model. Results of tests made at Ohio State University showing concentration of thrust at one corner of abutment indicate that common method of stress calculation is in error. Object of test was to determine magnitude, location and direction of resultant reaction at one abutment. Covers: adjustments and gages, loading, outline of theory, shear and torsion, tests of Columbus bridges, illustrated. CLYDE T. MORRIS, *Eng. News-Record*, 4-20-22, 2600 w. CS.

Architectural Models of Cardboard. Accurate model enables architect to see design as it will work out in three dimensions. Small-scale models advisable for reason that much of the detail may be represented by rendering. Cardboard models offer effective means of presentation, particularly in making of composite photograph—in which photograph of model of proposed building is combined with photograph of site and surroundings. HARVEY W. CORBETT, *Pencil Points*, 4-21, 800 w. (First in series.) HHH.

Effect of Construction on Heat Losses from Buildings. First article of series on effect of wall material and construction on heat losses. Covers walls and air spacing. S. HOMER WOODBRIDGE, *Heating & Ventilating Mag.*, 4-22, 3500 w. CS.

Education of Architects. Third of series by an experienced architect. In this article he discusses the value of travel and study abroad. Analyzes reasons for travel, best time to start, advises one year as about right and two years rather long. Student should take no camera but should do a lot of sketching. Travel-

ing for study said to be psychological and not fundamental. C. H. BLACKALL, *American Architect*, 4-12-22, 2200 w. EMCC.

Producing Plastic Magnesite. This material is widely used in the building material industry, especially on the West Coast, and many magnesite producing firms are catering to this growing demand and turning the material out in the plastic form. By governing the temperature during calcining, the raw magnesite loses its CO₂ gas and becomes caustic-burned or plastic magnesite. The article describes the raw material, method of getting it out of the ground, calcining it, controlling the calcining temperature and other similar matters. W. A. SCOTT, *Cement, Mill and Quarry*, 3-22, 750 w. MAH.

Building Costs. A tabulation of building costs is given for four buildings in California, six buildings in Arkansas, and four buildings in Alabama, describing type of construction, equipment, foundations, total cost, total cubic feet, cost per cubic foot, date of contract. Ninth of series of cost tables, figures for which are furnished by architects of the buildings mentioned. *Amer. Architect*, 4-26-22, 1000 w. EMCC.

CEREALS: MILLING

The Voice From the Tomb

THAT the old formulas for buying and selling wheat which were used some years ago by successful speculators are now of little value is indicated by attempting to apply the rule of an old-time trader to conditions today.

According to this rule, which is known among pit traders as the "Voice from the Tomb," the trader should: Sell wheat January 10th, buy wheat February 21st; sell wheat May 10th, buy wheat July 1st; sell wheat September 10th, buy wheat November 28th. But if this rule had been followed this year the result would have been disastrous. On January 10th Chicago May wheat was \$1.12, very near the low point; on Febru-

ary 21st May wheat was \$1.45, almost the high point. On May 10th the seller of May wheat would have been short at \$1.37½, whereas on May 12th the price was \$1.45.

Modern Miller points out that although in the old days markets acted with some degree of response to known conditions, violent market shifts are now the order of the day. Now, and ever since the war, the big and dominant price factors are at New York, Liverpool, and Buenos Aires. Although Chicago is still the clearing-house, it is said that for some time past the "inspiration" has come from New York City trade factors.

Handling Materials—Yeast Manufacture. Description of process used by Fleischmann Co., N. Y. City, by means of which they pack yeast for market. Combination of conveying equipment and automatic machinery keeps product clean, eliminates confusion in transportation of yeast, eliminates number of employees, lessens burden of management in plant, lessens overhead and has distinct advertising value. G. L. MONTGOMERY, *Chem. Met. Eng.*, 5-10-22, 1800 w. CJW.

Graham Flour Is Whole Wheat Flour. Data regarding its manufacture. Graham flour is made from well cleaned and dusted wheat ground but not bolted. Formula for making up Graham flour. Hard whole wheat flour (high

grade Canadian) 100, water 58 (variable), salt 1¼, malt extract 4, yeast 2, milk powder 3, shortening 2½ (weights in lbs.). A method of manipulating and bodifying product is also given. *Bakers Weekly*, 3-4-22. AS.

Breaking—Its Effect on Subsequent Operations. Poor breaking result of poor adjustment. Increased roll surface makes bran broader and cleaner, little or no bran chunks, middlings even and sharper and freer from fibre, little fine, greasy dust at head of mill, better and less break of flour; entire flour stream more even in texture, whiter, contains less fibrous matter and less ash and best baking qualities. Jos. H. BATES, *Millers Review*, 3-22. AS.

Biscuit and Cake Manufacture. Discussion of influence on finished product of several ingredients with special reference to action of milk. Following types of baked products considered: sweetened and unsweetened biscuits, drop cakes, pound cakes and sugar wafers. Shortening, sugar, invert sugar, eggs, leavens and flours treated in general way. W. PLATT, *Chem. Age*, 4-22, 2750 w. CJW.

Discoloration of Lye Hominy. Black discoloration of hominy is caused by formation of iron sulfide resulting from combination of iron from can with hydrogen sulfide, which is formed by every natural food when heated. Every type can will supply sufficient iron for this discoloration. To prevent this discoloration, alkalinity should be as low as possible. By means of scrubbing or abrasion process applied just after lying, outer layer of grain can be removed. This lowers alkalinity by removing outer layer into which lye has penetrated, aids in removing tips and bran layer, thus permitting shorter lying period and produces hominy with pleasing white appearance. E. E. KOHNAN, National Canners Association, Circular No. 2-L, 11 pp. (1922). CJW.

Science of Baking (XIII). Bakery sanitation, cleanliness and health of employees, janitor service, vermin, raw materials, machinery and equipment, care of bread, sanitation of bakery and sterilization during baking are stressed. *Northwestern Miller*, 3-22-22. AS.

Development of the Baking Industry. First of a series of illustrated articles dealing with the development of baking from a handcraft to a factory industry. A practical treatise on mechanical side of baking. First article, "In Earliest Times," of historical nature only. *Bakers Review*, 3-22. A.S.

Practical Science for the Baker—Fermentation. A treatise on alcoholic, acetic, lactic, butyric and viscous fermentations, and the role played by flour, temperature, yeast, mixing, milk, etc., in the same. *Bakers Review*, 3-22. AS.

Pictorial History of Milling (II). Age of pounding and rubbing. An interesting review of the history of milling profusely illustrated. *Northwestern Miller*, 3-22-22. AS.

The Cereal Movements Graphically Illustrated.—(U. S. Commerce Report).

DRUGS CHEMICALS

Copper Sulfate in Great Demand

ONE of the most important industrial chemicals to be affected by the general industrial improvement, says the *Chemical, Color and Oil Record*, is copper sulfate. The market is reported to be decidedly firm at the present time, with very little prime stock obtainable. This scarcity is believed to be due to successful competition with European producers which resulted in large Mediterranean sales. These were reinforced by sales to South America. And although probably the largest shipments have now been made, it should be remembered that May and June are the heaviest consuming

months at home, and it is predicted that the demand this year is likely to surpass all records. The loss of fruit last year from insects and fungus growths has convinced fruit growers of the necessity of spraying and the demand from the insecticide trade is likely to be heavy, especially as this is to be an "apple year."

The largest producers are taxing their capacity to fill requirements and are behind specifications. It is believed that prices will increase in the near future as a result of the unusual demand for copper sulfate.

Alcohol from Wood Waste. Comprehensive publication on subject. Includes apparatus and procedure, methods of analysis, yeasting and fermentation, effects of catalyzers, studies of different species of wood, by products, limitations, etc. Successful production of ethyl alcohol from wood waste seems to depend upon proper design, equipment and management of plant rather than upon improvement in chemical or fermentological features of process. Problem involves quick and efficient handling of large volumes of low-grade material under unusual technical conditions, perfecting of necessary acid-resisting pieces of apparatus, study of experience of plants that have been built and operated, and efficient utilization of material whose mere removal is now expense. Industry is unquestionably worthy of serious study of experimental and practical investigators of the utilization of forest products. F. W. KRESSMANN, *U. S. Dept. Agr., Bulletin 983* (1922), 100 pp. CJW.

Beverage Patent Medicines. Wine of pepsin found not to be sufficiently medicated, even when taken in large quantities, to produce any toxic effects other than obtained from alcohol present. Only physiological action produced by beef, iron and wine is obtained from alcohol it contains. Well-broiled and properly seasoned steak is recommended in its place. Findings have nothing to do with value of alcohol as solvent in pharmacy. J. E. GALLOWAY, *Northwestern Drug-gist*, 5-22, 1800 w. CJW.

Carbonic Acid Gas to Aid Plant Growth. Experiments carried out in France indicate that crops growing in open fields over which the air content of carbonic acid gas has been raised above the normal proportion show a greatly increased yield (100 to 300%) over fields not thus treated. Gas was obtained from blast furnaces and scrubbed to remove sulfur dioxide and other injurious gases. B. K. RALEIGH, *Compressed Air Mag.*, 4-22, 2000 w. CJW.

Sulfuric Acid. Packed cell process discussed. Plant consists essentially of source of sulfur dioxide, Glover tower, packed cells, Gay-Lussac towers, acid coolers, pumps, and fans. Chief points of interest are: Cost of plant for given tonnage is about 50-60% of that of equally well-built chamber plant. Cost

of operation no more and under some conditions less. Ground area is only 30-40% that for chamber plant of equal capacity. Process established much more rapidly and maintenance cost is probably lower, although this is not known since plant has been operating only two years. Details of design illustrated. E. L. LARSON, *Chem. Met. Eng.*, 5-3-22, 4000 w. CJW.

Chemical Fire Hazards. Deals with fire hazards of chemical processes. Covers: building construction, drying, grinding, evaporation, crystallization, filtration, distillation, autoclaving, reduction, nitration, chlorination, sublimation and hazardous chemicals. WILLIAM G. GRIER, *Drug & Chemical Markets*, 4-26-22, 2000 w. CS.

Sodium. Critical review of development of metallic sodium industry. Wide variety of processes used in its preparation based upon electrolysis of molten bath consisting of or containing sodium compound, such as caustic soda or salt. Original should be consulted. H. E. BATSFORD, *Chem. Met. Eng.*, 5-10-22, 5000 w. CJW.

Hydrogenated Naphthalenes. Technical production of hydrogenated naphthalenes discussed. Used in Germany as component of motor fuels, as illuminating oil, and as substitute for turpentine. May have slight use as solvent for resins, fats, rubber, etc. Most interest in America lies in possible use as basis for dyes and fine chemical industry. Hexalin, a further reduction product, is finding use for production of all kinds of soaps, for household, laundry and textile scouring operations, etc. R. G. FURNESS, *Chem. Age*, 4-22, 3000 w. CJW.

Residual Alum in Filtered Water. Chemistry of alum-coagulation process is represented by diagram which emphasizes both interdependence of various equilibria involved and importance of hydrogen ion. Data on alkalinity changes during treatment do not check with expected changes as ordinarily calculated. Data presented indicate in general less dissolved alumina in effluent than in influent. Amount of alumina in effluents did not exceed 2 mg. per liter. A. M. BYSWELL and G. P. EDWARDS, *Chem. Met. Eng.*, 5-3-22, 1700 w. CJW.

Isinglass. Isinglass is product composed of air or swimming bladders of certain fish. In Russia sounds are allowed to remain in water to remove blood and fatty matter, cut longitudinally into sheets and dried in sun. In this country material is macerated and then rolled into sheets. Jelly strength is fairly high; it is clear and colorless and produces glue of high adhesive value. Used in clarifying beverages, in court plaster, in cements for repairing pottery, etc., and somewhat in size where high luster is desired. R. H. BOGUE, *Chem. Age*, 4-22, 1500 w. CJW.

Brilliantines, Bandolines and Liquid Shampoos. Formulas given for separating and non-separating brilliantines, which serve to keep hair in place and giving it lustrous or brilliant appearance. Crystallized brilliantines are simply pomades of petrolatum and paraffin. Bandolines are employed entirely to smooth and fix hair. Basis largely tragacanth. Liquid shampoos essentially liquid soaps. Practically all oils except castor may be used. Corn oil is good, but lather is too light. Combination of coconut oil, cottonseed oil and stearic acid gives best lathering soap. Potassium carbonate is excellent detergent. Formula given, as well as perfume of low cost. E. R. JONES, *Bull. Pharmacy*, 5-22, 1500 w. CJW.

Ointment of Ammoniated Mercury. Wet process described. Formula calls for: mercuric chloride, 108 grams; ammonia water, 60 cc.; wool fat, anhydrous, 280 grams; white petrolatum, 500 c., and distilled water to make 1000 grams. Detailed directions given. E. R. JONES, *J. Am. Pharmaceutical Assn.*, 4-22, 750 w. CJW.

ELECTRICITY

Radio Sales Mount Steadily

A REPORT just issued by the Bureau of Research and Information of the *National Retail Dry Goods Association* indicates great possibilities in the merchandising of radio communication sets. Statistics contained in the report show that 56 radiophone supply companies were incorporated in New York during April; broadcasting stations of the 360-meter wave length now number well over 100; department store broadcasting stations now number about 13; licenses are now held by 10 newspaper broadcasting plants; manufacturers of radio apparatus, including 34 plants, which claim to produce complete sets, now number 202.

It is predicted that the annual volume of sales in each of many of the large Eastern department stores will average from \$200,000 to \$500,000. In regard to the type of set that will be used, the report goes on to say that unless the number of broadcasting stations increases so greatly that there is one within 25 miles of every home in the populous districts of the country, the sale of crystal sets ranging in cost from \$15 to \$40 and receiving only up to 25 miles will not be practical. It is believed that the higher-priced vacuum tube and amplifying sets, ranging in price from \$75 upward, will be most in demand.

Storage Batteries. Presence of certain amounts of impurities in electrolytes of storage cell has been studied to ascertain effect on electrical performance of cell. Only manganese and platinum, of metal tested, produced intense injury when present in minute quantities. With these two exceptions, none of impurities tested had lasting effect on cell voltage or on ampere hour capacity of charged battery. In various amounts certain impurities were found to be injurious, either by increasing rate of self discharge or decreasing life of plates. Zinc, nickel and tin in percentages tested were not detrimental to any of electrical characteristics. Results indicate that most of common metals and acids may be present in appreciable quantities without causing serious injury to cell. H. C. GILLETTE, *Trans. Am. Electrochem. Soc.*, 1922, 8 pp. CJW.

Lead Storage Battery. Cleanliness of greatest importance. Interior of battery compartment (other than lead) should be covered with acid-resisting paint. Corrosion of terminals may be prevented by application of grease or vaseline. Prompt removal of dilute acid from spray is essential to prevent creepage to trays and unprotected metal parts. Tops of cell should be wiped frequently with damp cloth. Normally water need not be added to battery oftener than once a week. Only distilled or analyzed water should be used. Correct specific gravity for locomotive batteries is usually from 1.27 to 1.28 at 70° Fahr. Local cell trouble most easily detected when giving battery an equalizing charge and may be indicated by low gravity of some cell or by its refusal to gas freely after long discharge. Suggestions for inspection. M. F. PACKARD, *Coal Age*, 5-4-22, 1200 w. CJW.

Nickel-Iron Storage Batteries. Exclude foreign material because cell containers are metallic and therefore conductors. If top of cell is covered with special oil, dry electrolyte crystals are avoided. Water lost should be replaced ordinarily every two or three days. Not introduced during charge. Semi-automatic filling device may be used. Before overcharging or renewing electrolyte, bring potential to zero. Cell may be injured if allowed to stand empty. Specific gravity of new electrolyte should be approximately 1.25,

which will be reduced to 1.17 to 1.19 by old electrolyte used for rinsing. M. F. PACKARD, *Coal Age*, 5-11-22, 1000 w. CJW.

Flashlight Characteristics. Various types of flashlights on market were investigated. Following conclusions were reached: Most useful light per dollar was obtained with long 2 or 3-cell flashlights, as extra cost for larger battery is nowhere near so great as extra life of light. No appreciable difference between soldered and seamless battery cases; for long shelf life latter is recommended. Large diameter lenses and reflectors should be avoided, except for extra long distance illumination, as their bulk and weight are a disadvantage. Light distribution is also poor. Conical reflectors give better light distribution than parabolic. It is recommended that more attention be given to the uniformity of construction of lamp bulbs for flashlights, since small displacement from its correct position will produce a large change in the distribution, with both kinds of reflectors. Candlepower on axis of flashlight may easily be reduced 50% by such a cause. T. SPOONER and C. F. ROYCE, *Elec. J.*, 4-22, 3500 w. IG.

Current Relay for Parallel Line Protection. New relay which, when inserted on parallel lines between generating stations, will allow the disconnection of the defective line without interrupting power service on the other line. Advantages obtained are: device operates on current alone and no source of potential is required. Very important on high-voltage lines where cost of potential transformers is considerable. Each current transformer may be grounded, thus affording maximum protection to the apparatus. Minimum number of relays is required as each relay is double acting. Instantaneous disconnection of defective line is possible. Same relay provides both differential and overload protection if desired. H. P. SLEEPER, *Elec. J.*, 4-22, 3500 w. IG.

Hawaii and Its Telephone System. Description of the very excellent telephone system which exists in this island. Very beautifully decorated building used as exchange. Z. REEVES, *Telephony*, 4-29-22, 4500 w. IG.

Inductive Interference and Electrolysis Relating to Railroad Electrification. Problems involved in inductive interference are complex, but the conditions are well understood, so that provision can be made for mitigating disturbances. In AC work great progress has been made in combating this disturbing element in railroad electrification. In a very late installation no interference was produced at all. Certain changes in AC railway equipment and in telephone equipment will go far to avoid difficulties in all cases. In DC work difficulties are overcome by the use of special structural changes in generators and by the addition of resonance shunts. Effects of corrosion by AC under ordinary conditions of operation may be regarded as negligible. DC railways have same tendency to corrosion on underground metal by electrolysis. Same kind of remedial measures which are employed in connection with street railways are applicable to high voltage systems. Cost should be part of cost of electrification. C. F. SCOTT, *Electric J.*, 4-22, 3500 w.

Control Equipments for the Frankford Elevated. This Philadelphia line includes all control equipments and features necessary for extending subway as well as elevated service, consequently some of it is unusual. Electro-pneumatic battery-operated unit switch control is incorporated. The article describes and illustrates practically all of this equipment, and lays marked emphasis on those departures from ordinary elevated road equipment. *Electric Railway Jour.*, 4-22-22, 2300 w. MAH.

Broadcasting Crop and Market News. What the United States Department of Agriculture is doing in the way of broadcasting weather, crop and market reports. The department sends this news over its leased wires to the broadcasting stations for distribution. J. C. GILBERT, *Telephony*, 4-8-22, 2400 w. IG.

Electricity in Coal Mines. Modern electrical installation with hydro-electric generating plant described. After eight years' operation, present cost of operation and maintenance is less than \$2,000 per month. Many safety precautions are taken. *Western Canada Coal Rev.*, 4-22, 1500 w. CJW.

Revamping Old Railroad Motors. Suggested that many improvements now part of newer types of motors can be incorporated in old types to reduce trouble and maintenance costs. Following must be taken into account: Essential to provide necessary and most efficient tools; and desirable to have several spare complete motors and armatures available. In replacing worn parts better grade of material should be substituted wherever possible to insure longer life. All improved methods of reconstruction should be adopted, including up-to-date processes and treatments. Heat treated shafts prevent trouble. Important to use good grade mica in repairing commutator. Banding of armatures should be carried out while hot, to obtain much tighter band, as it allows coils to be pulled down tightly in slots. When it becomes necessary to tin armature, it must be given thorough cleaning. Oil wells must be cleaned carefully. Adjustment of brush holders in accordance with six different points is described. Pinions should be heated for installation. J. S. DEAN, *Elec. Ry. Jour.*, 4-15-22, 5000 w. IG.

Copper Refining Electrolytes. In refining of metals by electrolytes influence of conductivity of electrolyte upon power consumption is of greatest importance. Practical conclusions are that copper content of refining electrolytes should be kept between 30 and 35 grams per liter and free sulfuric acid as high as economy permits up to 175 grams per liter. With higher free acid content solubility of copper sulfate decreases rapidly and, also, added increase in conductivity with more concentrated sulfuric acid is relatively not so rapid. Temperature of electrolyte should be as high as economy permits. The economical limit seems to be 55° C. Nickel and iron content of electrolyte should be kept as low as possible, as they greatly depress conductivity of electrolyte. E. F. KERN and M. Y. CHANG, *Trans. Am. Electrochem. Soc.*, 1922, 18 pp. CJW.

Electric Steam Generator. Outstanding characteristics are: It is the cheapest method of converting electric energy into heat; generator provides means of utilizing idle power and thus improves load factor; power company is able to sell surplus power for generation of steam; by utilization of much idle power conservation of natural resources is furthered; generator may be installed in very small space close to where steam is required. Simple, reliable, easily controlled, safe in operation and requires only attention of ordinary skilled man. H. DREVER and F. HOBSON, *Paper Trade J.*, 4-13-22, 1500 w. CJW.

Direct Current Armature Windings. I. A detailed description of the differences between the two important types of armature windings. Direct current windings are classed in accordance with the manner in which the inductors are wound on the armature core. Lap and wave winding of armatures are discussed. M. PHILLIPS, *Power Plant Eng.*, 4-15-22, 2500 w. IG.

Zinc Plating Solutions. Zinc plating baths, principal constituents of which are sulfate, fluoborate or zincate, show small throwing power although satisfactory

Electrolytic Cell Showing Pyrite as Anode. See "Mineral Sulfides as Source of Electric Energy" Digest at Right.

deposits may be obtained with sulfate baths when anode and cathode are plane and parallel to each other. Alkaline cyanide baths, containing sodium cyanide 53.2 grams; zinc cyanide, 59.2; sodium hydroxide, 43.8; sodium carbonate, 9.5; aluminium sulfate, 4.7; lignol, 11.8, and water 1000 cc., show high throwing power, moderately high efficiency, very low voltage and give continuously good results when operated under proper conditions. Proper conditions for this bath are: current density 2 amp. per sq. dm., 40° C., moderate stirring, anode composite of zinc and duriron, duriron surface forming 30 per cent of total anode surface. Use of addition agent is necessary. W. G. HORSCH and T. FUWA, *Trans. Am. Electrochem. Soc.*, 1922, 20 pp. CJW.

Electrodeposition of Zinc. Commercial electrolytic zinc is deposited from solutions which, from an electrochemical viewpoint, are to be considered impure and containing free acid. The continued deposition under such conditions depends upon maintenance of high hydrogen overvoltage at all points of cathode surface. Attained by maintenance at all points of substantial current density. By sufficiently increasing current density the hydrogen overvoltage for all metals examined may be made to exceed potential of zinc on hydrogen scale. Overvoltage of alloys lies between overvoltages of their constituents. Function of colloidal matter in electrolyte is to raise overvoltage of hydrogen. Practical work indicates optimum conditions to be free acid concentration of about 250 to 300 grams per liter with current density of about 100 ap. sq. ft. and presence of a minute quantity of gelatin or similar colloidal matter in solution. U. C. TAINTON, *Trans. Am. Electrochem. Soc.*, 1922, 20 pp. CJW.

Electric Drive in Rubber Mills. Advantages that are gained in the application of the electric drive to rubber mills. Three classes of machines must be considered. Various requirements of the different machines that are used in the rubber mill are discussed and it is shown how the electric motor meets these requirements. E. W. PILGRIM, *Rubber Age*, 4-10-22, 2500 w. IG.

Toll Center and New Toll Practice. Co-operation between toll center and tributary office facilitates placing of calls. B. PETERSON, *Telephony*, 4-29-22, 2500 w. IG.

Mineral Sulfides as Source of Electric Energy. Laboratory experiments show that cell of Bunsen type can be used with pyrite as anode in alkaline solution. Serves to demonstrate that certain mineral sulfides can be oxidized, giving up their oxidizing energy in form of electricity. As source of electricity pyrite has twice value of zinc, weight for weight. May be possible to oxidize sulfide in one cell and to use electricity generated to electroplate metal from solution that resulted from action in first cell. (Sketch.) G. N. LIBBY, *Eng. Min. J.-Press*, 4-22-22, 1000 w. CJW.

Mine-Fan Power Bills. After discussing various possibilities for driving mine fans, synchronous motors were considered. Low starting and pull-in torques of this type prohibited their use. This was overcome by closing chimney during start, or installing suitable clutch between fan and motor. Magnetic clutches used had time element of 90 seconds, though this period is not necessary to bring fan up to speed. This opens large field for synchronous motor. F. W. CRAMER and A. A. MACDONALD, *Coal Age*, 4-6-22, 2500 w. CJW.

Electrified Furniture. Pieces now manufactured for use in parlor, dining-room, bedroom and kitchen wired for service. Ten pieces of furniture in set recently wired as means of popularizing idea include bed, chiffonette, dresser, vanity table, sewing table, dining table, buffet, serving table, china closet, tea-wagon, kitchen table and kitchen cabinet. *Furniture J.*, 4-22, 1000 w. HHH.

Importance of Engineering in National Progress. Value of the engineer to society is discussed from the light of the recent new inventions which have made communication possible through the ether, besides in consideration of other discoveries which were made by engineers and scientists and on which humanity at large is dependent for its development and progress. C. F. SCOTT, *Electric J.*, 4-22, 5000 w. IG.

Welded Radio Towers. Towers 150 feet high at Peking, China, built largely of steel pipe with sleeve joints, electrically welded. Local conditions made a cheap, strong structure necessary and as structural steel was not available a suitable structure was built of the pipe. Figures show details. H. S. BEAR, *Eng. News Rec.*, 4-20-22, 1200 w. APS.

Building and Clearing of Circuits. To avoid loss of operator's time as well as circuit time, this simple rule should be followed, "Build to the toll center and clear to the last office reached." G. COAN, *Telephony*, 4-29-22, 500 w. IG.

Selling Utility Company to the Public. Description of methods used by Southern Bell Telephone and Telegraph Co. in selling its service to the public for the past 20 years. C. GILES, *Telephony*, 4-29-22, 5000 w. IG.

FUEL POWER

Distribution of Water Power

ALTHOUGH North America contains less than 15% of the water-power resources of the globe, it has developed more water power than all the rest of the world. It is estimated that about 41% of the developed water power is in the United States. European countries, particularly Germany, the territory comprised in the former empire of Austria-Hungary, Norway, Sweden, France, Italy and Switzerland, have also developed a relatively large percentage of their water power. Germany has the largest percentage.

The potential water power of the world is estimated at nearly 440 million horsepower when the streams are at ordi-

nary low-water stage, and the present installed capacity at a little more than 23 million horsepower. In the opinion of *Pacific Ports*, a reasonable estimate of the potential water power would amount to nearly four times the world's present total used power from all sources.

In the Eastern part of North America, a narrow, mountainous strip extending from the St. Lawrence River to the Gulf of Mexico affords most of the potential water power, but in the West, owing to the mountain ranges bordering the high plateau near the Pacific Coast water power is closely related to altitude and rainfall.

Fuel Economizers in Paper Mills. Decision as to whether or not economizer will "economize" rests entirely upon conditions which affect rate of heat absorption such as flue gases and feed-water temperature and plant conditions, such as amount of fuel burned, hours of operation and space available. In addition to saving fuel, economizer used with a hot-water heater, increases boiler capacity, life of boiler, and reduces scale in boiler. Types of construction, method of cleaning, operating code and care are discussed. G. E. WILLIAMSON and G. C. DERRY, *Paper Trade Jour.*, 5-4-22, 3000 w. CJW.

Classification of Coal. Parr, of Illinois, proposes to classify coal according to percentage of volatile matter and heating value per unit of pure coal substance.

Heating value may be calculated from formula $BTU=5000S/1-(1.08 \text{ ash} + 0.55S)$, in which S stands for sulphur. Following heating value limit proposed for simple classification: Brown lignite, heating value per pound of coal substance, 11,500 to 12,500 BTU; black lignite, 12,500 to 13,500; sub-bituminous, 13,500 to 14,000; Western bituminous, 14,000 to 15,000; Eastern bituminous, 15,000 to 16,000; anthracite, 15,500 to 16,000. More satisfactory classification is found by plotting heat value and percentage of volatile matter. See illustration. *Coal Age*, 5-11-22, 600 w. CJW.

High Steam Pressures or Pulverized Coal. Calculation of efficiency two methods of operating a public service steam plant of 100,000 kw. capacity indicated that with much lower capital costs,

even better thermal plant efficiency will be obtained with the use of pulverized coal and low-pressure steam than would be the case with the higher steam pressure and stoker-fired furnaces. F. A. SCHEFFLER, *J. Am. Inst. Elect. Engrs.*, 5-22, 7000 w. IG.

Recovering 90% of Coal. Experience has shown that economical pillar mining and maximum recovery of coal required that rooms be opened up only fast enough to provide for uninterrupted advance of pillar mining, that pillars be mined promptly upon completion of rooms, that line of pillar mining be carried forward in one direction until sufficient area was completely mined out to cause good break of overlying sandstones, that direction of breakline be varied as little as possible within reasonable limits and that barrier and other pillars be of sufficient size not only to protect workings properly, but to admit of being satisfactorily mined when time came to mine them. Recovery increases as thickness decreases. Statistics of recovery given for all mines in Pocahontas field. T. H. CLAGETT, *Coal Age*, 5-4-22, 3000 w. CJW.

Power Plant to Use Pulverized Fuel Exclusively. Description of Milwaukee Elec. Ry. & Light Company's new Lakeside power plant, using pulverized fuel. Article describes progress of construction work and its unusual features, general arrangement of plant with outstanding features differing from usual traction power plants, difference in equipment and in operating methods, and gives much other detail of interest and value. *Electric Traction*, 4-22, 7400 w. MAH.

Petroleum Technology. Author, director of research, American Petroleum Institute, outlines avenues of development in petroleum technology. Grouped under following heads with number of problems stated: Production, 7; transportation and storage, 7; refining, 29; colloid chemistry, 6; marketing and utilization problems, 22. These need combined resources of nation for their satisfactory solution. *Chem. Age*, 4-22; *J. Ind. Eng. Chem.*, 5-22, 4000 w. CJW.

Great Western Power Company's 165,000 Volt Transmission Line. An interesting description of transmission line which is located in California. W. A. SCOTT, *Eng. World*, 4-22, 1000 w. IG.

How It Is Proposed to Classify Coal, as Described in Accompanying Digest.—
(*Coal Age*).

Solid Absorbents for Natural Gas. Adsorption process during 1921 produced 30% of gasoline from natural gas. Activated charcoal, silica gel and iron gel have been proposed as solid absorbents. Yields are greater, product better and installation and operating costs lower by use of these materials. Future casinghead gas plants will be combination compression and charcoal processes. Solid absorbents will also be used in refinery practice to strip tail gas of its gasoline

IRON STEEL

A Pacific Coast Steel Industry?

THE greatest problem of the metal industry in the West, according to the *Journal of Electricity and Western Industry*, is to find in the Western country a coking coal free from sulphur, or to devise a commercially profitable means of refining iron ore without the use of coking coal. Throughout the West there are huge deposits of iron ore which are easily available for mining and transportation. And it is believed that the opportunity offered for expansion of the iron and steel industry is sufficiently important to warrant definite appropriations by the Western States for the study of the problem. Not only is the cost of raw materials no higher

than at the Eastern iron and steel centers, but owing to climatic conditions and other advantages of this region, it is possible to carry on the manufacture of all kinds of metal products under the most economical conditions, thus lowering the price of the finished products. Moreover the West is favorably located in regard to markets, both at home and abroad. A large portion of the export trade in iron is likely to be with China and Japan, and there is a greater demand for farm machinery west of the Mississippi River than in the East, where machinery is now manufactured.

Zirconium Steel. About 193 heats of steel, containing in various combinations the principal variable elements of carbon, silicon, nickel, aluminum, titanium, zirconium, cerium, boron, copper, cobalt, uranium, molybdenum, chromium, and tungsten were studied. None of steels presented any difficulty in rolling into plates except those containing boron. Usual mechanical and impact tests were carried out. Steel containing 0.40 to 0.50% carbon, 1 to 1.5% silicon, 3 to 3.25% nickel and 0.60 to 0.80% manganese and deoxidized with simple deoxidizer, such as aluminum, can be produced having tensile strength of 300,000 pounds per square inch with excellent ductility and toughness. Recommended for structural steel. Same properties obtained with aid of additional elements, but not necessary to use these more costly elements. Zirconium acts primarily as scavenger and when not removed as part of slag remains in steel in form of square, bright yellow inclusions not directly visible at magnifications lower than 500 X. It is not considered that these inclusions can be very beneficial and if segregated into groups and rolled out into thin plate-like streaks they may be detrimental. Of other elements chromium, tungsten, vanadium and molybdenum go into solution and produce martensitic pattern in air-cooled specimens. Boron forms complex eutectic, probably that of iron-carbon-boron compound with iron. This

eutectic is fusible at temperatures ordinarily used in rolling, but at slightly lower temperatures steel containing boron can be rolled successfully. G. K. BURGESS and R. W. WOODWARD, *Tech. Paper, Bureau of Standards*, No. 207 (1922), 54 pp. CJW.

Inspecting Gears, Etc., Under Microscope. Invention for use in connection with Hartness comparator for testing gear teeth is known as Projection Comparator. The advantages are pointed out of thus determining the regularity of the teeth, one after another, the symmetry of the teeth, etc. The details of obtaining the image and reflecting it onto a ground-glass screen and the manipulations during testing. RALPH E. FLANDERS, *Iron Age*, 4-27-22, 1500 w. APS.

Methods of Handling and Heat Treating Springs. Leaf springs for vehicles are made in tremendous quantities, and must be turned out quickly, yet of very high and unusually even quality. This has brought about the design and construction of machinery which will handle the springs automatically through all the heat-treating processes, so they go in simply as flat steel plates and come out, some distance away, as finished, tempered springs. This extensive article describes all the processes by which this is done, with details of furnace sizes, shapes, sections, equipment, etc. *Canadian Machinery*, 2-23-22, 4000 w. MAH.

Carburization. Carburizing ability of different forms of carbon decreases as ash content increases. Denser varieties of carbon are more effective than more porous ones. Artificial graphite, resistor carbon, petroleum coke, and coal-tar coke give better results than higher ash cokes or charcoal. Presence of slag decreases rate of carburization by tending to prevent contact between metal and carburizer. Action more pronounced as acidity of slag increases. Silicon carbide is excellent medium for adding both silicon and carbon to iron. Cannot be used for introducing all carbon because too much silicon would be added and cost would be too high. Silicon or phosphorus has no effect upon rate or degree of carburization, but manganese seems to increase both, while sulfur probably decreases both. C. E. WILLIAMS and C. E. SIMS, *Trans. Am. Electrochem. Soc.*, 1922, 20 pp. CJW.

Welding in the Steel Plant. How the acetylene, electric arc and thermit welds are applied to special maintenance problems. Gives the details of use and application of each method, the procedure to be followed in each case and the special field for each process. Discussion by members of Association of Iron and Steel Electrical Engineers. Gives details on welding of nickel steel, costs on various welding processes, carbon losses in welding cast iron, influences of various type arcs, use of coated rods, fluxes, etc. WALTER PETRY, *Welding Eng.*, 4-22, 10,000 w. APS.

Acid Open Hearth Process for Gun Steel and Fine Steel. Part II. Continuation of description of details of this kind of work. To be continued. W. P. BARBA and HENRY M. HOWE. *Blast Furnace & Steel Plant*, 4-22, 5000 w. APS.

Good and Bad Years in Iron, with the Years 1896, 1903 and 1915 Shown as Normal. From figures gathered by the *American Metal Market*.

MACHINERY

Machine Tool Development Activities

THE rapid development in machine tool design during the last ten years is encouraging, not only to machine tool manufacturers, but to manufacturers in other lines of industry. In every case where machinery has taken the place of hand labor there has been a tremendous saving in time, energy and money. Trucks and commercial vehicles owe much of their development to machine tool and gasoline engine designers. Even in road building and track laying, the machine is beginning to supersede the laborer to a large extent.

"More and more, the art of machine tool design is becoming specialized," says *Canadian Machinery*. "Engineers are devoting their entire time to some particular branch of industry. The result is that these men become experts in that particular branch, and produce machines of the highest efficiency. . . . Instead of using the old-time pickaxe, we now have the steam-driven pavement breaker, and air tools for varied purposes.

Hand and Machine Lapped Surfaces through the Microscope. In the manufacture of surface gages, plug gages, gage blocks, and other precision work, the creation of an exact surface is highly important—in fact its attainment or failure to attain spell success or failure, as the case may be. This means that lapping is freely used, and also that resort must be had to the microscope for checking some of the surfaces produced. This article presents views (through the microscope) of various surfaces, produced by various methods, and gives an interesting set of diagrams to correspond with the qualities of these surfaces, ranging from fair grinding to exceptionally fine machine lapping. *Machinery*, 4-22, 1400 w. MAH.

Machine Wear Affects Quality of Product. Author argues that machines must be installed properly and aligned accurately, shocks must be minimized, parts which might sag must be supported, and other points must be provided against in the installation and care of machine tools, otherwise the product will be of poor quality, that is, inaccurate, out of true, of wrong size, or wrong otherwise. Other points stressed are: Strength of tool frames, weak tables, proportions of slideways, wear across the corners, local wear on long slides, increase of wearing surfaces, wear of screw threads, etc. **FRED HORNER**, *Can. Machinery*, 3-9-22, 6100 w. MAH.

Designing Screw Threads for Bolts and Nuts. Stresses on small screws and bolts are largely due to the individual judgment of the mechanic working on or with them, rather than to those internal stresses set up by the separate machine parts. Consequently, small screws can not be designed so accurately for their work as larger ones. For the latter, the designer must consider those stresses due to internal forces, those due to shock loads, failures due to thread stripping, and others. The author goes into the reasoning, and then into the mathematics of all the possible cases under these heads, developing empirical formulas for the use of the student of screw thread

The air compressor is usually self-contained, and in addition we have the electric welder busily engaged making rail connections."

The cotton industry is the latest to feel the benefit of modern machinery. An electrically operated picker has recently been placed in operation, with which it is possible for one person to gather from 400 to 700 lbs. of cotton per day, as compared with 70 to 150 lbs. by hand.

In view of all these improvements, it seems quite possible that the building industry, which uses such a great amount of hand labor, may be the next to profit from the ingenuity of the machine tool designers. For if a machine can be invented to pick cotton, it does not seem unreasonable to believe that machines may be produced which will perform the mechanical operations in construction work for which human laborers are now employed.

design. **L. T. RUTLEDGE**, *Can. Machinery*, 3-9-22, 4900 w. MAH.

Gear Construction Material and Application. General discussion of all the possible materials from which gears may be made, with advantages and limitations of each. More space is given to the unusual materials than to the usual metals, as for instance rawhide, fibrem bakelite-micarta, etc. Author tells how to machine these, which kind of keys must be used, best types of cutters, etc. Also takes up metallic gears, especially in brass and die-cast gears which require no machining. **CHESTER B. HAMILTON**,

Can. Machinery, 3-13-22, 3100 w. MAH.

Reducing Operating Costs by Careful Planning. Description of prominent Canadian plant, making computing scales, which have many parts to be machined. The method followed in routing the material through the shop is described, forms used are shown, the splendid lighting and its benefits, the arrangement and selection of the tools, the jigs and fixtures, in short, every feature tending toward simplicity and low production cost. **J. H. MOORE**, *Can. Machinery*, 4-6-22, 2600 w. MAH.

Germany Scores Again with a "Greatest"
This is the largest scoop shovel in the world—larger even than the giant shovels which dug the Culebra cut in the Panama Canal. It is a mechanical digger and was constructed by Krupp and exhibited at Essen. (*International*)

CEMENT-STONE-BRICK

Profit from Stone Screenings

ACCORDING to *Cement, Mill and Quarry*, sand, gravel and crushed stone manufacturers have an opportunity to utilize in their entirety the product of the pit or quarry, and by such utilization to confer a lasting benefit upon their communities. It is pointed out that in all such operations there is an abundance of fines produced for which the sale is slow, necessitating the piling up of such screening, or the accumulation of large bodies of sand for which there is no immediate call. And although it costs as much to produce a ton of screenings or fines as it does to produce a ton of commercial stone, the demand for the one absorbs the supply, while there

is a very limited demand for the other. The same thing holds true, generally speaking, with respect to sand- and gravel-producing plants.

Some concerns have solved this problem by putting in machinery for the manufacture of block, brick tile and pipe, making concrete units out of what is ordinarily waste, and thus enlarging the turnover without a large investment. It is believed that such a plan would prove profitable in many cases, especially in Chicago, where immense piles of stone screenings have accumulated and where the demand for block products is very large.

Improving Concrete Sand by Classification. Classification is separation of grains into sizes by currents of water. Without adding any complications to plant, product may be varied as to modulus of fineness and percentage of voids. This allows operator to meet specifications for which his sand would otherwise be unavailable. Also makes two or more merchantable products from sand that would have little value in unclassified condition. Describes methods and results. E. SHAW, *Cement, Mill & Quarry*, 4-20-22, 2000 w. CS.

Producing Gravel with Few Men. Description of equipment and operation of gravel plant at Columbus, Ohio, designed to produce 1500 tons daily, with only seven men—a superintendent, one man each at pit, hoist, crushing plant and washing plant, and two men loading trucks and cars. Low labor costs are outstanding feature this plant. Has storage capacity 30,000 tons. Searchlights for night work. Duplication of practically every piece of equipment as insurance against breakdowns. STEPHEN STEPANIAN, *Rock Products*, 4-22-22, 2500 w. CS.

Sand-Lime Brick and Mortar. Starting with the suggestion that recent tests seem to indicate that brick strength is materially increased—from the usual 20% to 75%—if a mortar is used which unites with the brick and produces what is practically a monolith wall, this author argues for greater use of both sand-lime brick on the one hand and sand-lime mortar on the other, and especially for the two used in combination. He discusses general field construction conditions, strength of mortars and usual tests, proper bedding of the brick and influence of this on final strength. R. P. BROWN, *Rock Products*, 3-25-22, 2900 w. MAH.

Waste Production in Slate Production. Government investigator points out to slate producers ways in which present wastes can be reduced. Some of these are avoidance of imperfections in quarrying so as to produce approximately 100% perfect slate, reduction in use of explosives to a minimum, thus reducing costs, and in shattered slate manufacture of a greater variety of products, the slate not available for blackboards, roofing, etc., being turned out in other

forms, avoidance of rehandling to cut costs, simplification of process, etc. OLIVER BOWLES, *Cement, Mill and Quarry*, 3-22, 1700 w. MAH.

Facts About Concrete Floors. Importance of interior concrete floor finish should be given more consideration in building specifications. Floors should be wetted, same as pavements and roadways, to prevent "dusting." For slight additional care in construction returns measured in service rendered by floor are increased over 50% for practically same investment in materials and labor. J. E. FREEMAN, *Architect & Engineer*, 4-22, 2000 w. CS.

Specifications for Concrete Buildings. Continuation of editorial discussion of how properly to write specifications for buildings and other structures made of Portland cement concrete. *American Architect*, 4-12-22, 3000 w. EMCC.

Cast Concrete Building Block. Gives experience of company starting with small capital, and success achieved by quality products and perseverance. H. R. WALLACE, *Concrete Products*, 4-22, 2000 w. CS.

Sawyer System of Concrete House Construction. Gives description of Sawyer system, using interlocking horizontal precast slabs keyed to vertical studs, which form light walls of ample strength. Gives clear illustrations of construction details. *Concrete Products*, 4-22, 1500 w. CS.

Column Sizes in Reinforced Concrete Skyscrapers. Discussion of interior concrete columns for skyscraper building, special reference to Hide & Leather building, New York. First-floor columns, 38-in. diameter, carry load 1,280,000 pounds. Reinforced concrete structural frames increase in strength with age. *Bldgs. & Bldg. Management*, 4-17-22, 2500 w. CS.

How a State Highway Department Inspects Its Material. Illinois Highway Department makes personal inspection at plants by competent inspectors. Results give satisfaction to both sides. Covers: duties of inspectors, investigational work, present projects, results of tests of patented preparations, setting of concrete at low temperatures, curing, fatigue, graduation of aggregates. H. F. CLEMMER, *Rock Products*, 4-8-22, 2500 w. CS.

Range of Cement Prices Over Last Nine Years.—(Engineering News-Record)

LUMBER-WOOD PRODUCTS

Southern Floods Mean Stock Shortage

A SCARCITY of hardwood and corresponding high values are likely to continue well into another year as a result of the recent floods in the timberlands of Missouri, Tennessee, Arkansas, Mississippi and Louisiana. It is believed that the total duration of inactivity in the mills is likely to be at least sixty days; and that this shutdown will result in a shortage of dry stock at the time of greatest demand, in October, November and December next.

The *Lumber Trade Journal* points out that the anomaly of the present situation is in the "distress" lumber back of the levees. The owners are making the greatest efforts to move from danger points in case the levees break, and there is a considerable quantity of this lumber moving at so-called "attrac-

tive" prices. But it is predicted that this condition of affairs will not last long, and as soon as the worst is over, the price on this lumber will probably be increased sufficiently to more than make up the total loss accruing to the whole territory due to "distress" sales.

It is reported that some of the big buyers are signing for their reasonable seasonal wants later and that considerable blocks have been changing hands at wide ranges of prices. Since it all depends upon the location of the producer as to how the water affects him, and his ability to guarantee shipments, it is said that some buyers have paid premiums for the guarantee, at the same time that "distress" lumber was being offered at lower prices.

Hickory Wood. Laboratory tests show that, weight for weight, sound hickory has same strength, toughness and resistance to shock, regardless of whether it is red, white or mixed red and white. Reliable indication of strength of hickory is its density. Heavier piece will be found to have better strength properties. Fairly reliable visual guide to strength is found in proportion of summer wood appearing on end of piece. Number of growth rings per inch also affords some means of grading hickory. Few growth rings per inch indicate stronger and tougher piece. Best hickory shows an oily or glossy side-grain surface when smoothly finished. Forest Products Lab., Technical Note 171, 4-22. CJW.

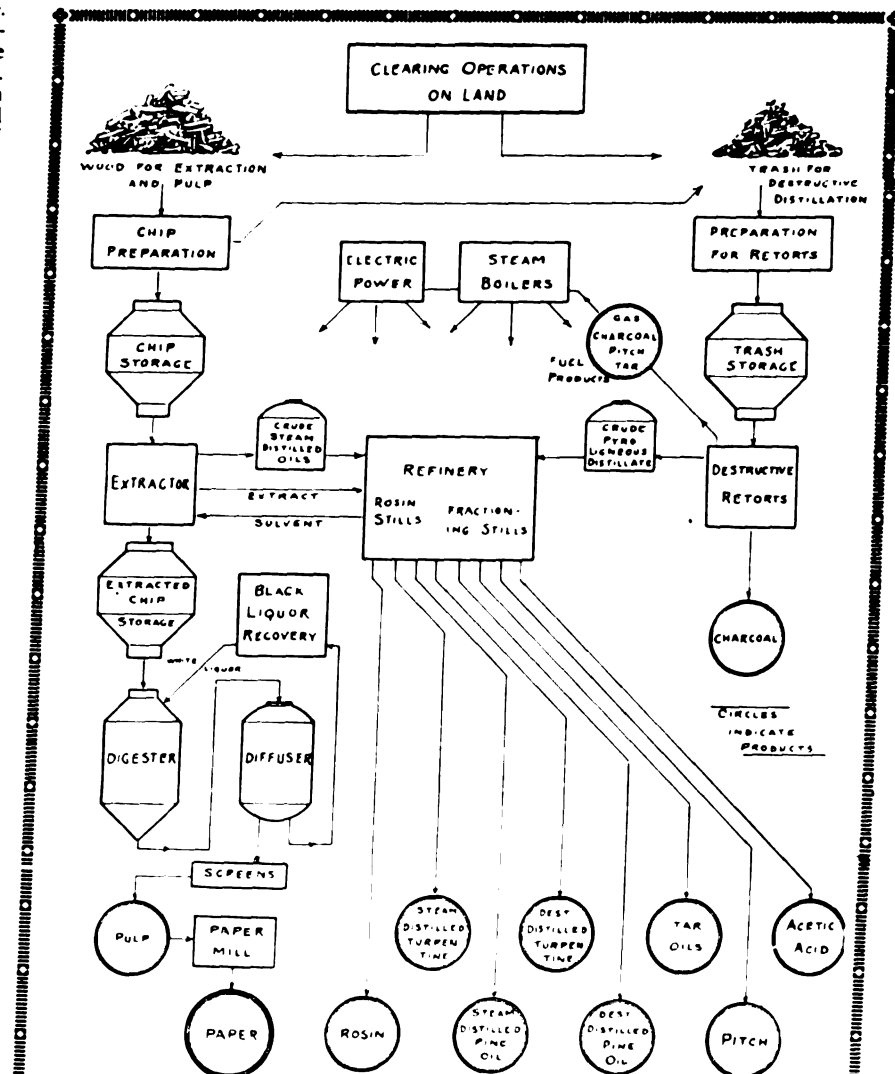

Startling Forest Facts. Critical situation is facing the owners and lessees of pulp lands in Canada, this author says. The continued slash of logging is threatening the destruction of all the forests, and adding to this the fire risk. The Canadian pulp and paper industries should take immediate action to reduce consumption of timber, to reduce cutting, to prevent or reduce materially the export of timber to the United States to improve fire protection, etc. Quite pessimistic in tone. FRANK J. D. BARNJUM, *Jour. of Commerce*, 3-17-22, 3800 w. MAH.

Proper Packing of Furniture. High freight rates paid by furniture trade partly due to fact that claims, because of poor packing, are exceptionally high. Consignments must be adequately protected against unavoidable shocks—coupling of freight cars, switching of cars over hump, taking out slack in freight train when starting, transferring at freight platforms. Delay caused by settling of claims for damaged furniture results in annoyance, and often loss of customer's trade. ALBERT W. LUHR, *Furniture Mfr. and Artisan*, 3-22. HHH.

Redwood Block Pavements. Redwood well suited for paving and flooring; needs no preservative to retard decay. Before laying, blocks should be dipped in boiling asphaltum cement to make them moistureproof and antiseptic and cement together fibres, which become toughened and exceedingly resistant to traffic abrasion. Thin coat of asphalt

cement and sand gives further precaution against wear. Should be laid upon concrete foundation and all details of construction should be strictly in accord

with specifications prepared by an engineer experienced with this particular character of work. *Timberman*, 4-22, 500 w. HHH.

Products That Can Be Manufactured from Waste of Cut-Over Pine Lands
(Paper Mill & Wood Pulp News)

New Industrial Uses of Zinc

ALTHOUGH the chief uses of zinc are for galvanizing, for zinc oxide and for brass making, the principal chance for expansion of the market lies in the use of zinc plates and sheets. The newest and most interesting outlet for zinc is as a roofing and siding material, and for leaders and eaves-troughs. The chief argument against zinc for this use—its high coefficient of expansion—has been overcome by the use of corrugations, slip joints, and improved methods of hanging, and it is now only necessary to convince the buying public that the old objections no longer hold.

Increased use of automobiles have greatly enlarged the demand for zinc oxide as a filler to improve the resiliency and durability of automobile tires, for which its only competitor of importance is carbon black. It is also a valuable paint pigment, sharing the field with lead.

Brass contains varying percentages of zinc and the demand from this industry is beginning to be more apparent owing to the fact that the large tonnages of war scrap are practically exhausted. It is believed that some of the copper propaganda will affect zinc favorably in the field of brass consumers.

Another use for zinc that promises to increase its consumption is that of zinc shingles for houses. They are as permanent as the house itself and in the present designs the butt shingle effect of wood is secured. An oxidized surface of a slate gray color has been perfected which harmonizes well with ordinary forms of construction and finish, although the colored effects possible with copper cannot be secured, except by painting; but the cost is only half that of copper and very little more than demanded for a good wood shingle.

World's Tin Supply. Brief history of tin and its sources with full description of methods of mining in Malay Peninsula and East Indies. American tin output is negligible. Statistics of tin trade. Smelters are chiefly in Malaya, Britain and United States; later smelts Bolivian concentrates. At present world is overstocked with tin accumulation. List of uses and tonnage of tin consumed for each use. Table of prices of tin since 1910. Comprehensive. Photographs and figures. RICHARD HOADLEY TINGLEY, *Raw Material*, 4-22, 4500 w. APS.

Y Alloy. This is aluminum-copper-nickel-magnesium (92.5:4.2:1.5) which gives alloy as light as any of stronger aluminum alloys and is distinctly superior to most in ease of manufacture. Its great superiority lies in very remarkable resistance to corrosion and its entire immunity from intercrystalline cracking under prolonged loading. Sheets prepared by cold rolling 1/4-in. plate, reducing thickness 10% in each stage and separating stages by quenching from 480° C. of 0.05 in. thickness, show an ultimate strength of 58,000 to 61,000 lb. per sq. in., and elongation of 16 to 18% in 2 in. The buckling stress was found to be 30,600 lbs. per sq. in., 13% higher than duralumin. *Chem. Met. Eng.*, 4-26-22, 1600 w. CJW.

Commercial Welding on High-Pressure Boilers. Detailed instructions to the welder for difficult work in the plates and sheets of boilers which are to be subjected to high pressures. Guesswork is eliminated and the exact procedure is laid down. Either gas or electric processes may be used, but gas is given the preference by the author. Welding flue sheets, patching flue sheets, welding fire boxes, butt welding side sheets, other parts of the work. EDWARD H. HEIDEL, *Can. Machinery*, 4-6-22, 1425 w. MAH.

Standards for Testing Welds. Digest of papers by English authorities on welding, discussing desirability of adopting certain test standards. One gives as only useful test the selection and destruction of a certain percentage of finished

articles. Chemical analysis and physical tests. Bending test considered good. Tests in ship building and repairing. The nature of the welding operation. Much general discussion of standards. *Welding Eng.*, 4-22, 5000 w. APS.

Nonferrous Metal Industry. Aluminum. Zinc. Uses of aluminum, hardening by zinc and copper additions; use of manganese to facilitate casting. Casting practice, rolling. Zinc. Uses, qualities. Substitution for brass, increasing consumption and development of new uses. A. LINCOLN SCOTT, *Brass World*, 4-22, 2000 w. APS.

Aluminum Alloys. Digest of eleventh alloys research report to Institution of Mechanical Engineers, England, on light aluminum alloys. One of the most important alloys developed is so-called "A" alloy (77:20:3 Al:Zn:Cu). Sheet 0.05 in. thick had a yield point of 60,500 pounds per sq. in., tensile strength of 74,000 pounds and elongation of 16 per cent in 2 inches. Another alloy, "E" (with 0.5 per cent magnesium and 2.5 per cent copper), after extrusion, hot-rolling, quenching from 400° C. and aging, showed tensile strength of 91,100 pounds and an elongation of 9 per cent in 2 in. Constitution of these alloys. *Chem. Met. Eng.*, 4-12-22, 4000 w. CJW.

Research Work on Zinc and Zinc Alloys. Alloys with very high zinc content have replaced brass with favorable results. Iron as alloying metal gives alloy of value in resisting pressure but not for resisting pulling stresses. Aluminum alloys with zinc have not proved of value. WALLACE DENT WILLIAMS, *Canadian Foundryman*, 4-22, 2500 w. APS.

Roasting Copper Ores. Discussion of method of sulfatizing roasting of semi-oxidized ore. Ore is heated to reacting temperature (below ignition point of sulfur in ore). During this stage, direct oxidation of copper and iron sulfides occurs. Temperature is then gradually elevated to 1100° F., during which copper sulfide is oxidized to the sulfate and oxide, while part reacts with ferrous sulfate to form copper sulfate and iron oxide. Results depend upon temperature control. To obtain high total solubility of copper it is necessary to sulfatize practically all sulfide copper; that is, roasting of sulfidized direct to oxide does not give satisfactory results. P. R. MIDDLETON, *Eng. Min. J.-Press*, 4-15-22, 1500 w. CJW.

Possibilities in Pipe Welding. In piping contractor's shop fittings formerly requiring expensive patterns are made from otherwise scrap material. Tools and machines are repaired and gears restored. Cutting torch cuts more quickly than pipe cutter. Header (photograph) produced by welding is practically impossible by older methods. Van Stone joints made in field or in shop on larger sizes than shop machine can handle. Details of aligning pipe line prior to welding. Cutting of flanges. Cost of welding outfits. Excellent photographs of operations. FREDERICK K. DAVIS, *Heating & Ventilating Mag.*, 4-22, 1800 w. APS.

Pouring Manganese Bronze Propeller Wheel. Manganese bronze, more properly known as high-tension brass, is copper-zinc alloy with small amounts of manganese, tin, iron, aluminum, nickel, etc. Description of furnace and melting practice. Casting operation. Pyrometric control of metal in furnace, control of zinc content, tapping furnace, teeming metal, skimming metal in mold and feeding casting as contraction occurs. WESLEY J. LAMBERT, *Canadian Foundryman*, 4-22, 3000 w. APS.

X-Rays and Atomic Structure. Simple discussion of X-ray spectra of the elements, atomic numbers, etc. ROGERS D. RUSK, *Brass World*, 4-22, 750 w. APS.

MINING

Helping the Mining Industry

THERE is a natural increase in the use of any product due to increasing population with the consequent increase in consuming power. In many industries the producing capacity has been increased by war needs beyond normal consuming capacity and beyond the consuming capacity which may be expected to arise as a result of natural growth. In many departments mining interests have felt the influence. The non-ferrous metal producers are in this class. We brought out in a previous notice the entire dislocation of the industries due to lack of balance between the mining, smelting, refining and fabrication of these metals and the terrific waste sure to result from the attempts of all parties to survive.

A means out of the difficulty is to find new uses for the

metals which will produce enough consumption demand to absorb increasing amounts of the productive capacity. In addition to the new uses for aluminum alloys in structural work, a definite attempt is being made by strictly educational propaganda through newspapers and technical and trade publications to acquaint the public and professional man with valuable but neglected uses of certain metals, especially copper and zinc. In housebuilding, copper and zinc have a distinct place, both pure and as brass. Copper roofs in sheet form or as shingles are permanent, beautiful and less expensive in the long run. Copper or zinc gutters and leaders are similarly permanent. Brass hot-water fixtures are best from the point of view of upkeep and ultimate cost and convenience.

Metal Mine Fire Fighting. Fire-fighting squad should consist of 5 members. Need following apparatus: 5 oxygen rescue, 5 extra cylinders, 5 portable electric lamps, 4 or more large cylinders of oxygen, 1 high pressure pump for loading small cylinders, supply of caustic soda, extra goggles, rubber parts, etc., which would cost at 1920 prices, about \$2,200. Training desirable, which can be maintained for annual cost of about \$250. Standardization also desirable, since fire in adjoining property is dangerous and necessity of interchange of parts may become necessary. W. CONIBEAR, *Arizona Mining J.*, 4-15-22, 1500 w. CJW.

Automatic Mine Car. Car has been designed combining feature of automatic door release and body latch with positive locking devices on both pieces. This combines mechanisms which will unlatch rear of car body from truck, independently of car door latch; keep car unlocked as long as desired, and latch same automatically after dumping car. Also unlatch car door automatically for either end or side dump, only when car has been raised to inclination of 13° from horizontal. Description of construction. L. S. FARNHAM, *Eng. Min. J.-Press*, 4-15-22, 800 w. CJW.

Mine Fires. Principal reasons for mine fires are: Ignition of coal seam from shot; ignition of firedamp from shot or miner's lamp, ignition of coal from electric power lines, and self-heating or spontaneous combustion. Article discusses latter in detail. Self-heating of coal due to thickness of seam, crushing of pillars, faults, roof and other conditions such as uneven and incomplete settlement of goaf, gob or waste, leaving of timber in goaf, presence of coal and timber in packs, etc. Conclusions of English committee given. R. Z. VIRGIN, *Coal Trade Bul.*, 5-1-22, 2500 w. CJW.

Loss of Bituminous Coal. Recovery of coal varies from 40 to 95 per cent, depending upon many conditions. Survey of 12 mines in 1914-1915 showed average recovery of 41 per cent. One great source of loss is pillar coal. Unless

pillars are recovered quickly and pillar drawing forms definite part of initial planning, very little pillar coal will be recovered. Depends upon safety, geological conditions, operating and financial conditions. Fourteen conclusions and suggestions regarding this work are given. H. H. STOEK, *Coal Trade Bul.*, 4-17-22, 2500 w. CJW.

Accidents on Rope Haulage Roads. Of all operations none is able to show better return for money spent on safety measures than average mine haulage system. Mechanical means for reducing

accidents are inexpensive and easily installed. In Great Britain separate traveling roads for men compulsory. Refuge holes next in importance. Commonsense precaution is to anneal couplings every 6 mos. Common types of chain hooks described. Haulage ropes fitted with rope sockets should be recapped every six months, and strength of socket should not be less than 16% of that of rope. Discussion of contrivances for scotching or holding car in use on steep incline, haulage by "rakes," etc. H. BRIGGS, *Coal Trade Bul.*, 4-1-22, 1600 w., 20 figs. CJW.

Fluctuation of the price of platinum, in dollars per troy ounce.—(The Trader).

PAPER

\$70,000,000 Liquidation in Pulp and Pulpwood

ACCORDING to a survey made by the American Paper and Pulp Association the business depression of 1921 resulted in losses aggregating \$70,000,000 to the paper industry of the United States. The Association review says: "Pulpwood and wood pulp rank as the heaviest elements of loss. In small quantities, pulpwood can today be purchased at from eleven dollars to twelve dollars per cord less than at the peak of the highest price period. In other words, that figure is the loss in the process of manufacturing this wood into paper. Even for the sake of conservation, cutting in half the twelve dollars per cord difference between purchase prices of wood and present value based on the sale price of

the paper, from which it is made, there has been sustained a loss of six dollars per cord, indicating a loss on wood alone of about \$35,000,000. A single big company wrote off a loss of \$6,000,000 on its wood. The pulp situation has paralleled the wood as a cause of losses. On the basis of consumption of 1,300,000 tons of pulp annually, and again assuming a minimum figure of thirty dollars per ton as the loss in value, the total pulp loss reaches a total loss of \$35,000,000.

"However, it is believed that the writing off of such a tremendous loss in a single year is the best possible evidence that the paper industry has completed its period of liquidation and is ready to start on the road back to prosperity

Uniformity of Basis Weights of Paper.

Detailed procedures are given of system of records to maintain uniformity of basis of weights. Includes: taking set of representative samples from reels or rolls during previous day or shift; gathering samples and machine room data; arrangement of samples in sequence; preparation of preliminary guide from which to make adding machine "slips"; making of "slips"; checking of weights by rapid method for "scale error"; correction of sample weights by individual weighing if incorrect; deductive calculations for each division of shift; calculation of daily and accumulative averages; calculation of laboratory tests; contract monthly statements. Example. P. K. BAIRD, *Paper Trade J.*, 4-13-22, 2000 W. CJW.

Lighting Paper Mills. Extended discussion of lighting requirements of all rooms of pulp and paper mills, illustrated by diagrams and illustrations. Benefits cited are: safer working conditions, increased production in manual and semi-manual operations, reduction of eyestrain, improved morale, sanitary working conditions, neater mill. J. H. KURLANDER, *Paper Trade J.*, 4-13-22, 3000 w. CJW.

Mechanical Pulp. Efficient production depends upon several factors: variation of average grinding pressure, temperature of stock in pit and character of grindstone surface can be controlled. Present discussion directed to means of operating any given water-wheel installation most efficiently from viewpoint of speed control. Follows discussion of Meyer governors with photographs and

Production of Paper by principal countries, 1921.	
UNITED STATES	1,000,000
GERMANY	1,000,000
CANADA	1,000,000
SWEDEN	1,000,000
AUSTRIA-HUNGARY	1,000,000
RUSSIA	1,000,000
FRANCE	1,000,000
ENGLAND	1,000,000
NET EXPORTS	1,000,000
TOTAL	1,000,000

(From Standard Daily Trade Service)

charts. Factors are: maintaining most efficient turbine speed, thus enabling grinder to produce 10% more and better pulp; uniform speed practically eliminates grindstone breakage; and in general improves quality of pulp produced and increases yield per cord. Centrifugal pump alone is not satisfactory pulp grinder control. A. F. MEYER, *Paper Trade J.*, 4-13-22, 4000 w. CJW.

Sedimentation Control of Groundwood.

Baker Mfg. Co. have devised freeness test outfit which enables determination of accurate moisture content of sample in 1½ min., and whole test can be made in 3 min. Stock is centrifuged for 1 min. Certain weight of this stock is mixed with water enough to completely fill cylinder and freeness determined by amount of water discharged through side orifice. Freeness of stock depends upon wood, temperature and white-water. Results of tests. W. A. MONROE, *Paper Trade J.*, 4-13-22, 1000 w. CJW.

Sulfur in Waste of Sulfite Liquor.

Careful study of the titration for free sulfur dioxide and loosely combined sulfur dioxide has been made and conditions laid down for most accurate titrations. Splitting out of sulfur dioxide by means of alkali has been investigated and it has been found that there are two kinds of sulfur dioxide split out. One is split out at room temperature and the other only when temperature is elevated. After four hours boiling of sulfite waste liquor the sulfur dioxide content reaches a nearly constant figure. Of the loosely combined one-third is removed by boiling. G. BARKSKY, *Paper Trade J.*, 4-13-22, 2000 w. CJW.

Hydrating Machinery. Discussion of use of manganese steel in beater and washer rolls. Advantages claimed are: roll is practically non-destructible, shows very little wear, segmental bar tends to "draw" fiber more with less power consumption, absence of wood filling in roll insures same bucket capacity, as there is no trouble from raised fillings; manganese tackle can be used on finest papers, as it does not rust; not affected by heat and gives paper superior in finish, strength and general appearance, as proved on rag, rope, jute and wood papers. G. L. BIDWELL, *Paper Trade J.*, 4-13-22; *Paper Industry*, 4-22; *Paper Mill*, 4-15-22, 1200 w. CJW.

Color of Resin Size. Color of resin size emulsion has marked effect on color of finished product. Other factors being same, color of size will vary directly in accordance with amount of resin. As temperature of size is increased the final color will be darker. To obtain creamy white, temperature should be kept at least under 140° F. Temperature of water used of importance. Where white color is desired care must be taken to put exact amount of water in emulsion tank at start. Use of such controls as charts, standard emulsions, liquid standards discussed. F. BECKER, *Paper Trade J.*, 4-13-22, 750 w. CJW.

PRINTING PUBLISHING

Paper Standardization Will Help Printer

THE standardization program recently adopted by the seven national associations in the printing and allied industries marks an important step forward in the elimination of paper wastes and the stabilization of costs. The chief aims of this program are to cut out unnecessary grades, weights and sizes, reduce the number of colors, finishes and watermarks, and to increase production. The seven associations responsible for the move include the United Typothetae of America, the National Association of Stationers and Manufacturers, the National Association of Employing Lithographers, the National Association of Steel and Copper Plate Engravers, the Asso-

ciation of National Advertisers, the National Association of Purchasing Agents, and Direct Mail Advertising Association.

Just as the manufacturer reduces costs by limiting his line, by cutting out useless grades, styles and varieties, so in the printing industry better quality, greater uniformity, and quicker deliveries are secured through standardization. To the printer, lithographer and stationer it means the elimination of dead stocks and the reduction of overhead. The paper merchant can speed up the turnover of his capital and the mill can improve quality, equalize production throughout the year and purchase materials on a surer basis.

Real Economy in Printing Plant. Economy much needed in average printing plant. Poorly etched photo-engraving expensive. Requires too much time for pressman to work it up on press. Mistake in operating "squeeze-up" style of pressroom. Correct make-ready saves wear and tear on type. Only best craftsmen should be in charge of type cases and equipment. No economy in rushing out cheap product at cut prices. Best black printing inks made from lamp-black, produced by process of burning natural-gas. Necessary to have best quality in colored printing inks, especially bright reds. Plated paper of inferior grade loses time and money. Quality means economy. ROBERT F. SALADE, *Printing Art*, 5-22, 3000 w. MBB.

Hints for Letter and Commercial Designers. Every pictorial composition should have some interest point which together with other components of picture must form pleasing totality. Real difficulty of imaginary picture-making is putting first or standard object, which will serve as comparison for dimensions of others. After locating horizontal line marking point of sight, locate station point determining line of distance. To locate second vanishing point, draw line from first point to station point and from there at right angles to horizontal line. Using these lines as basis, it is possible to obtain necessary lines for scale of buildings and other objects. J. C. STRICKLAND, *Nat'l Lithographer*, 4-22, 900 w. MBB.

Lack of Sales Analysis Weakens Much Classified Copy. Difficulty with classified copy is lack of analysis of sales problems. Price appeal is too much stressed, with no sense of fact that both rich and poor desire best goods or service their purse can afford. Criticism of instruction ads, making negative appeal; positive appeal thought to pull better. *Editor and Publisher*, 4-15-22, 1000 w. MBB.

Selling Quality Printing as Well as Quality Paper. Manufacturers of paper believe quality of paper adds distinction to printed matter, but printing can make paper look what it isn't; either better or worse. JOHN T. BARTLETT, *Amer. Printer*, 5-5-22, 700 w. MBB.

A Handy Type Chart

This type chart will be found useful by the advertising man and printer for computing the number of square inches that will be consumed by a given number of words—any number from 9 to 80,000. Lay a thread or rule across from the size of type in column A to the number of words in column B, and the intersection through column C gives the number of square inches that will be required. For example: How many square inches will be required to set 5,000 words in 5-point 'lead type? The dotted line, drawn across the chart, shows how it is done. —(By W. F. Schaphoist, M. E., in *The American Printer*).

Color Printing. Among points in conduct of American printmaking, thought of interest to visiting British printers, was extensive advertising used in States to boost trade, measure of success in standardizing sizes and qualities, welfare work, bigger and faster machinery used and workers' willingness to accommodate themselves in order that biggest possible output may be obtained. *Nat'l Lithographer*, 4-22, 600 w. MBB.

Modern Design: Its Application for Learners in Sketch Department. The vignette on the average can-label is very crude, only up-to-date lithograph houses keeping this material to standard which belongs to high-class goods. In drawing vignette, finish rough sketch carefully, apply color first in masses. Avoid lack of balance between light and dark parts. Apply first modeling shade, half as deep as the darkest shadow and brightest light. Carefully match color tones in sketch so objects will have natural appearance. ALFRED HONSCHOFF, *Nat'l Lithographer*, 4-22, 1000 w. MBB.

What a Foreman Ought to Know. Foreman of composing-room should know principles of stone work, his linotype and monotype output, watch carefully all delays in presswork due to okeing positions and readers' proofs, keeping them to minimum; observe closely justification of his forms, preventing workup on press, read job tickets closely, do distribution as religiously as typesetting. CHARLES HEALE, *Amer. Printer*, 5-5-22, 800 w. MBB.

Facts Concerning Presswork and Press-room Workers. Advantage in locking up a heading or small form on cylinder press to put strip of postcard bristol about one-eighth inch by six inches between chase and furniture on bed of press. Less mixing of inks the better. Use expanding roller trucks, also automatic feeders desirable. A. J. TOMLIN, *Amer. Printer*, 5-5-22, 1000 w. MBB.

Capitalizing Words in Headings. European and Latin-American printers have advantage over American in simplicity of rules governing use or non-use of capital letters in display headings; using all-capitals for topping heads, subheads put in smaller capitals, or lower-cased with only such capitalization as done in body matter. JACOB BACKES, *Amer. Printer*, 5-5-22, 900 w. MBB.

OILS · PETROLEUM

Fifteen Petroleum Problems

THE solution of fifteen important problems of the petroleum industry is now being sought by the special research committee of the Petroleum Section of the American Chemical Society. The list of problems to be solved, according to the *Chemical, Color and Oil Record*, include: Preparation of rational specifications for petroleum products, these specifications to be based upon the results of actual research work; standardization of analytical methods and apparatus for petroleum products testing and analysis; utilization of wider range of motor fuels in mobile types of engines; more efficient utilization of heavy oils in Diesel and other engines of the heavy oil type; investigation as to the actual need of highly refining gasoline for motor fuel; development of higher efficiency in internal combustion motors through use of selected fuels or through use of chemically treated fuels

which will stand higher compressions; modification of the design of carburetors and internal combustion engines to enable the use of less volatile gasoline and investigation of the relations between volatility, specific gravity and distillation analysis to performance of blended mixtures and straight cuts; a study of the fundamental causes of carbon formation in cylinders; elimination of polymerized products in cylinders; combustion characteristics of different hydrocarbon series; ignition temperature, detonation, etc.; effect of volatility on fuel consumption; an unbiased scientific study of the different base crudes and the fundamental causes thereof; a study of the relative tendency of different lubricants to absorb fuel and become excessively diluted; scientific study of numerous problems in lubrication; recovery and purification of used lubricating oils in large industrial plants.

When Is Oil "Good." A petroleum product is good or bad according to whether it suits or does not suit the condition for which it is used. Particular attention is paid to the motor lubricants. Dilution of the oil, carburization, etc., are discussed. Immediate solution of the problem as far as the internal combustion engine is concerned seems to be to treat the mixed lubricating oil and fuel, while the engine is in operation, and to return the fuel portion to the cylinders to be consumed, the regenerated lubricating oil to go back to the crank case. Process is now being worked out. Apparatus has been perfected to such a point that it has been under observation on trucks, tractors and passenger cars for several years. Results obtained have been that the oil in the engine has been kept at approximately its original body. All the fuel which leaked into the crank case and has been caught by the lubricant has been removed and the recovered fuel has been converted into power in the cylinders, thereby eliminating a double loss. Oil thinned down by the fuel has been regenerated and cleaned, and after cooling has been returned to the crank case. W. F. PARRISH, *Oil News*, 4-5-22, 2800 w. IG.

China Wood Oil. Collecting and shipment of china wood oil. Testing described, and properties of the various grades discussed. Due to the fact that limits of the constants are quite wide the adulteration of the oil to varying extents can be practiced without a chemical analysis proving the admixture of certain vegetable oils. The analysis of the oil is very difficult to carry out and it is likewise difficult to interpret the results obtained thereby. In order to be able to determine the quality of china wood oil, the analyst must be familiar with the oil itself. Experience is necessary to interpret the results of the analysis correctly. G. H. PICKARD, *Amer. Paint Jour.*, 4-3-22, 2000 w. IG.

Thermal Problems of Petroleum Refining. Discussion of petroleum refining practice from combustion engineer's viewpoint. Oil refining is as yet most isolated of all process industries. Except for laboratory, where there are

Relative rates of growth of domestic consumption of principal petroleum products, 1899-1920, showing dominant growth of demand for gasoline.—From *Mining and Metallurgy*.

many chemists that have had experience in other fields, refineries are too much dependent on inbred talent. Result is seen in comparison between chemical and operating phases of refining. While large number of new products were developed in recent years, mechanical features of methods of production are same, changes being rather addition to and not improvements of practice of past. Many refinery operations could be greatly improved by adaptation or by pooling by different plants of experiences in general operating features. "Give-and-take" policy as demonstrated in metallurgy, for example, would not only help abolish existing troubles, but would raise standard of operating efficiency and result in better product at less cost. L. A. MEKLER, *Chem. Met. Eng.*, 4-26-22, 3000 w. CJW.

Tank Development. Description of the

methods used by a large refinery in constructing its tanks. Selection of sites, building of tanks, piping, fire protection, etc., are covered. W. SAMANS, *Oil News*, 4-5-22, 5000 w. IG.

Destructive Distillation of Oil Shale. Some factors affecting products of destructive distillation of oil shale are discussed. Not yet determined how much of dissimilarity in oils evolved is due to character of included organic materials or how greatly amount and character of minerals associated with organic matter may affect oils. Influence of physical structure of shale, temperature lag and rate of heat supply are discussed, and possible commercial applications of the laboratory results. L. C. KARRICK, *Chemical Age*, 3-22, 2000 w. CJW.

Viscosity of Petroleum Oils. As general rule, viscosity of any mixture of paraffin and petroleum oil is intermediate between the two components. This is only approximate, since mixtures of the two in which the oil is of about equal viscosity were slightly less viscous than either of the constituents. Paraffin wax, when dissolved in oil, behaves like an oil of low viscosity at temperatures considerably below its melting point. E. W. DEAN and M. B. COOKE, *J. Ind. Eng. Chem.*, 5-22, 2500 w. CJW.

Possible Origin of Oil. It is conjectured that the absence of paraffine and other hydrocarbons in the soil indicates the existence of an intermediate organic compound between the complex plant compounds and the petroleum hydrocarbons. Much evidence points to humus acids. On this basis a theory is developed which may account for the formation of oil. C. C. RAE, *Oildom*, 4-22, 3000 w. IG.

RUBBER • PLASTICS

Acceleration in the Rubber Industry

ALTHOUGH rubber production in general has not yet reached normal, a consistent improvement is noticeable. According to *The Rubber Age*, the tire industry is in a more healthy condition than it has been for some time. Practically every company manufacturing tires in Akron is said to have reported increases in production, and in many cases, sales. One of the largest plants recently added 1000 men in order to bring its daily output up to 24,000 tires a day. This company and two larger ones also reported that they were within

10,000 to 12,000 of their daily production capacity. Sales in mechanical goods have shown substantial gains; products such as rubber packing are in better demand and public service and transportation corporations are beginning to increase their purchases. Garden hose, rubberized clothing, summer footwear, rubber bathing caps and suits are selling well for future delivery. It is believed that during the second and third quarters of the year, which are the best seasons for the industry, the volume of sales of goods will increase.

Vulcanization Tests on Hexamethylene Tetramine. Experiments were made with object of ascertaining the physical properties of cured rubber when varying quantities of hexamethylene tetramine are added to a formula in which varying quantities of sulphur are used. The basic formula was smoked sheet 100 parts, zinc oxide 3 parts. Various percentages of sulphur and hexamethylene tetramine are added thereto. It was found that in general 1% of hexamethylene tetramine is the most satisfactory quantity to use for the stock containing 3% or more of sulphur. C. S. WILLIAMS, *India Rubber World*, 4-22, 1000 w. IG.

Handling Cloth Wrappers in Rubber Factories. It is shown how the standardization and the proper care of the wrappers insure a more smoothly run-

ning organization, a neater shop, and a larger saving of material, time and labor. The wrappers referred to are used to cover rolls of gum stock, calendered sheets and rubberized fabric until ready for use. Various kinds of wrappers are classified. Care should be taken to prevent the tearing of the wrapper. *India Rubber World*, 4-22, 2500 w. IG.

Cost of Rubber Linoleum Manufacture. Some interesting figures are given showing the cost of manufacturing rubber linoleum. It is estimated that twelve layers of material 20 yards long by 2 yards wide can be produced in an hour. Working on a two-day shift of 16 hours per day, with a five-day week, 48 weeks to the year, the annual output would be 1,843,200 yds. Vulcanization by the Beachy process is estimated to cost two cents per sq. yd. *Rubber*, 2-22, 1000 w.

Ideal Omnium Rubber Works, Ltd., 1940. An imaginative story of how a rubber works will operate two decades hence, written in the style of a conversational narrative as the visitor is being conducted through the plant. P. SCHRIDOWITZ, *India Rubber World*, 4-22, 2000 w. IG.

Rubber Creations in Moving Picture Production. Description of the manufacture of all sorts of rubber properties used in taking moving pictures, such as flexible lamp-posts, clubs, etc. *India Rubber World*, 4-22. IG.

Glossary of Terms and Words Used in Rubber Industry—(XIII). Definition of the various terms used in manufacture of pneumatic tires and their use. H. C. PETERSON, *India Rubber World*, 4-22, 3000 w. IG.

Gentlemen:

As you have been doing extensive work for us over a period of a year or more, we are pleased to express our favorable opinion of your Organization and the work it has been doing for us. Your service to us has covered a broad field, drawing, we believe, on all divisions of the Organization and comprising the entire scope of your service.

An appreciation of the value of your service prompts a desire on our part to assist you in furthering your progress. To this end we invite you to refer prospective clients to us for pertinent and detailed comment on the benefits to be derived from your several specializations in the field of Industrial Engineering.

Very truly yours,

SUGAR CONFECTIONERY

Steady Increase in Per Capita Consumption

THE large surplus of sugar in Cuba is likely to prevent any marked advance in price for some time to come, according to *The Soda Dispenser*. Efforts of interested parties both in the United States and Cuba to restrict the present season's crop or limit the quantity exported to the United States with a view to obtaining higher prices in this country have proved unsuccessful. But it is expected that the prevailing low prices will encourage larger consumption of sugar and that this, with the anticipated increase in the purchasing power of Europe, will absorb the surplus and result in a gradual stiffening of prices. European May requirements remain uncovered, and advices from Germany indicate that a considerable quantity of imported sugar will be needed, owing

to the development of the chocolate industry, the full employment of various other industries consuming sugar, and the prohibition of the imports of pineapples, bananas and other fruits which were received in large quantities before the war.

Sugar consumption in the United States for 1921 was 5,274,255 tons, equal to 97.8 pounds per capita. This is nearly twenty-six per cent greater than the average for the ten-year period ending in 1920 and 6.4 pounds greater than in 1920, which was higher than any preceding year. It is estimated that the United States consumed more than twenty-eight per cent of the world's production. It is believed that in the sugar industries, as in others, profit will be obtained, not so much from increased prices as from greater economy in production.

Burning of Sugar Cane Fields. Experiment to determine losses by delay in harvesting cane from large accidental or incendiary fires, including total loss in sugar, and loss in weight of cane, showed that time was not a factor, as rate of deterioration shows only gradual increase as time since burning increased. Little difference in loss between burnt cane cut at once and such cane allowed to stand until milled. Rate of loss in cut burnt cane tends to diminish as cane becomes dryer. When burnt cane stands, density of juice tends to slight decrease; cut at once, shows decided increase in density of juice. Juices of burnt cane, whether cut or standing, dropped in purity at about same rate. Quality ratio (tons of cane per sugar) of cut burnt cane is better than that of standing burnt cane. *Sugar*, 5-22, 1000 w. MBB.

British Guiana Sugar Industry. Though expensive layout is necessary in British Guiana sugar estates, to keep out excess water, yet in dry weather water shortage is acute. Present method of raising water level to height needed to submerge soil, running water off at intervals, is very wasteful. Advantage of flooding is resulting improvement in soil texture, with oxidation changes taking place where reduction processes would be more likely to be expected. Soil becomes porous, though no change is apparent in content of nitrogen, upon which growth depends largely. Percentage acreage of bourbon and other varieties of cane planted now amounts to only 13%, while 78% is occupied by Demeeaea seedlings produced in botanic gardens, 9% of seedling varieties being raised by other countries and local estates. Aspect of cane in relation to disease is comparatively satisfactory. *J. CRABTREE, Sugar*, 5-22, 2000 w. MBB.

Manufactured Food—A Timely Observation. Principal factors for great advantages of commercial production of food are: purchase of raw material on a large scale, permitting utmost reduction in price of any commodity, utilization of by-products, reducing ultimate cost of main production, substitution of human labor by ingeniously constructed ma-

chinery, and liberal use of artificial, but harmless, ingredients. With commercial production, housewife's task is made comparatively simple. Essential for growth of this industry that retailer and consumer receive better understanding of proper aims of "bona fide" food industry. *BENNO LOWY, Western Confectioner*, 5-22, 800 w. MBB.

Mannose. Five hundred grams ivory nut shavings or sawdust (after treatment with dilute sodium hydroxide, washing and drying) are digested with 75% sulfuric acid for one day, then dissolved in water to make 5.5 liters. This mixture is boiled for 2.5 hrs., neutralized with barium carbonate, concentrated and sugar crystallized from glacial acetic acid, yield being 42% to 45% of treated meal. *E. P. CLARK, Scientific Papers, Bureau of Standards*, No. 429 (1922), 2 pp. CJW.

Advertising Ice Cream. Quality most important point. Newspaper most valuable; billboards good; attractive window cards have their place. Children are great boosters—gives methods. *WILL TERRY, Ice Cream Trade Jour.*, 4-22, 1200 w. WRR.

Facts and Fallacies Concerning Overrun. Considerable amount of overrun in ice cream necessary and important, but too high overrun produces inferior product. Salesmanship will sell, but not resell. All consumers want mellow, velvety texture. Real trouble is after it

The Far West Likes Soft Drinks.—*(Western Confectioner).*

leaves the plant—if it softens up it will shrink frightfully in dipping. Give tests to show loss. Amount of solids should be kept up. *L. S. WORK, Ice Cream Trade Jour.*, 4-22, 1600 w. WRR.

Results of Proper Covering of Cane. Hawaii is offsetting labor shortage by saving work in the field. Problem of weeds solved by special paper, surfaced with asphalt, making it waterproof and heat-absorbent, thus forcing growth of cane. Ten per cent labor shortage can be entirely relieved by paper covering 37% of crop area; difference in productivity of row-covered area is direct gain of 39.24% per acre, obtained with 16.56 days per acre less labor than was required on uncovered area. *W. D. HORNADAY, Sugar*, 5-22, 900 w. MBB.

Ice Cream Sanitary Considerations. Bacterial content is index to its sanitary quality. High quality must contain low count. Bacteria come from two sources: Materials used; cream; gelatine, sugar, vanilla, condensed milk. Outside contamination: air, utensils, employees. Influence of freezing, hardening and holding on bacterial count. Manufacture of low-count ice cream. *H. G. PALMER, Ice Cream Trade Jour.*, 4-22, 1800 w. WRR.

Extraction of Oil from Vegetable Matter. Vegetable oil industry today represents an investment of approximately \$200,000,000. The normal annual production of oil is 2.5 billion pounds, equivalent to the crushing of 5.8 million tons of seeds and other oil-bearing vegetable matter. It has been found that the manner of the application of pressure in the process of oil extraction bears a very important relation to the efficiency of the process and also to the economy of the cloth used for covering the cake. High-pressure yielding plunger pump has been designed and has proved to be one of the most decided improvements made in recent times. Detailed description of the apparatus is given. No safety or controlling devices are required when this pump is used. Wear and tear on cloth is at a minimum. *J. DAVIDSON, Mechanical Engineering*, 5-1-22, 2500 w. IG.

Cotton Prices Likely to Advance

THAT a considerable improvement in both raw cotton and the cotton goods industry may soon be expected is evidenced by a review of the fluctuation of raw cotton and cotton goods prices since 1919. A comparison of conditions in the cotton industry with general business conditions appears to indicate that cotton has passed through a cycle similar to that of general business. Between 1919 and 1920 both raw cotton and cotton piece-goods passed from a relatively low to a relatively high point, relapsed to a second low point in 1921 and rallied again in August and September. Advances and declines in speculation have also preceded similar changes in the

price of cotton goods. This reaction is not always immediate; a comparison of cotton goods prices with speculation during the period from 1903 to 1914 indicates that cotton prices did not increase until eight or ten months after speculation had begun. But even allowing for this period of time to elapse, the outlook is encouraging to the cotton industry. Speculation, beginning last August, presaged the improvement of business recorded since February, and it is believed that cotton goods prices will respond to these circumstances as they have in the past, and that an extended advance may be expected before next fall, and perhaps before the middle of the summer.

Reduction Vat Dyes. First dye of this type was indigo. Insoluble in water, reduction to indigo white renders it soluble. Preparation of dye bath requires: dyestuff, monopole oil or similar product to air in formation of smooth paste, caustic soda to aid solution of dyestuff, sodium hyposulfite to reduce dyestuff and salt to produce better exhaustion of color. Amounts depend upon dyestuff used. Vat dyestuffs well adapted for production of colored effects on white material. In dyeing woollens alkalinity should be kept low as possible. W. E. HADLEY, *Am. Dyestuff Reporter*, 4-24-22, 500 w. CJW.

Linen Fabrics. Direct colors generally used for dyeing. Penetration of vat dyes not very good. Examples of formulas are given. Finishing should al-

ways be carried out on cooled material. Moisture plays an important part. Examples. Shrinking carried out by simply wetting fabric with water and hanging in suitable place until moisture evaporates. Process must be repeated to be successful. Unshrinkable linen not yet produced. D. WILTERN, *Canadian Dyer Color User*, 4-22, 1000 w. CJW.

Dyeing Wool in Cold Baths. Experiments reported at 50-60° C. Good solubility and great tinctorial power are requisites for dyeing from cold baths. Basic and acid dyes should be as fast as ordinary. Mordant colors are hardly likely to be as fast. Cold dyeing is more likely to be level than hot dyeing. Extension of time greatest objection. *Canadian Dyer and Color User*, 4-22, 750 w. CJW.

Scouring of Textile. Standard scour on heavily oiled woollens described in which 20 gallons for each piece in machine is used, this run off as soon as indications of slipping on rollers were observed; treatment repeated as often as necessary. Advantages were cheapness by economy of soap, little color bleeding, softness and handle were conserved. Worsteds did not require so drastic treatment. Materials for construction of textile plant discussed. Aluminium deserves more attention. J. SCHOFIELD, *Am. Dyestuff Reporter*, 4-24-22, 2000 w. CJW.

Fibre Knowledge. Shows that its lack is cause of many mill failures; method of acquiring knowledge; characteristics of a good cotton and method of identification; things to be avoided; spinning qualities and use of micro-photographs of typical samples. JAMES McDOWELL, *Textile World*, 4-8-22, 2000 w. WRR.

Utilization of X-Rays in Examination of Textiles. Description of a radiographic study of yarns and fabrics that are used in the manufacture of tires, mechanical rubber goods and other rubber products. The importance of such a study in determining the value of these products is told. *India Rubber World*, 4-22, 2500 w. IG.

Cotton Manufacturing Industry and Cooperative Management. Description of large plant, with complete village, including church, school, club and general social and welfare organization, in existence for ten years. ROBER WILLIAM BOYS, *Textile American*, 4-22, 4000 w. WRR.

Wood in Connection with Dyehouses and Bleacheries. Roofs of dye places are very susceptible to certain destructive influences. Fungus; shows how fungus acts; best woods to use; importance of design of woof. JOSEPH WOODMAN, *Textile Colorist*, 4-22, 3000 w. To be continued. WRR.

Analytical Study of Cotton Production, Wages, Prices and Exports for a Half Century.

House Organ Headquarters

**WILL HELP YOU ESTABLISH THAT EMPLOYEE PUBLICATION
OR SALES ORGAN YOU ARE THINKING ABOUT**

Ours is a Planning, Writing, Editing, Printing and Art Service Distinctively Qualified for House Organ Work.

Tell us how much you want to spend and we'll give you a definite idea of the publication that amount will buy. And we will furnish a Magazine or Paper that will fit into your needs.

We Specialize in Industrial and Institutional Publicity Designed to Reach the Employee

Our Service Eliminates Costly Experimentation

Have You Seen the Blue Pencil?

Send 30 cents in postage for a sample copy

The only Trade Paper devoted exclusively to the subject of Employee Publications, House Organs, etc. It deals in a Practical way with every phase of publication work.

Planning, editing, gathering news, articles and information, how to buy and use art and engravings, etc. It contains 80 and sometimes 96 pages of information.

HOUSE ORGAN HEADQUARTERS, 187 Montague Street, Brooklyn, N. Y.

Facts! Facts! Facts!

THINK of the multitude of business facts with which the man of affairs must be familiar.

Facts—thousands and thousands of them—flow by him daily; all flowing together down the stream of our daily, weekly and monthly journalism; a gigantic log-jam of events.

And out of all that mass of complexity, unmarked, hidden from sight, lurk the few facts—the very few—that are really significant; the few that are the key-logs which would release the mass. Who has time to find them, or the skill to pry them loose?

This is the Reason for the Industrial Digest

In each of the 30 important branches of industry and commerce The Industrial Digest employs a man who makes it his business to keep accurately and thoroughly informed regarding all developments of importance. Every two weeks he prepares a careful report; and at a meeting these 30 reports are carefully compared, the individual items are evaluated and a master report is prepared.

A Master Report on Business

This master report is, therefore, a comprehensive survey of American finance, commerce and industry. It makes up, in fact, this issue of The Industrial Digest which you hold in your hands.

The expense of preparing The Industrial Digest is tens of thousands of dollars a year, but since the cost is divided over thousands of business executives, the service is offered to you at the cost of \$5 per year.

In view of the fact that the same service could not be rendered by a department of your own at less than a prohibitive cost, this sum is indeed ridiculously small. It is in no sense a measure of the value of the service to you.

THE INDUSTRIAL DIGEST,
25 West 45th St.,
New York City.

Please send your fortnightly survey of American industry and commerce to me for one year. I enclose five dollars, check or money order.

Earnings from Efficiency

AN example of the increased railway efficiency which has taken place since private operation replaced Government operation, the railroads of the country handled 7 7/10 per cent revenue ton miles more than they did in 1914, according to the President of the American Railway Association. As an indication of what may still be accomplished in the matter of traffic efficiency, this executive believes that the field for econ-

omy lies in two main directions: First, heavier car loading, and second more mileage per car per day. When it is understood that one ton more per carload is equivalent to adding 80,000 freight cars to the supply now available and that one mile additional per operating day is tantamount to adding 100,000 freight cars to the supply, it will be seen that even a slight increase in efficiency will affect the earning ability.

Australia and Its Railways. About 27,300 miles railways, about half 3 ft. 6 in. gauge, rest 4 ft. 8½ in. and 5 ft. 3 in. Sheep and cattle raising and grain require much mileage per unit of population; Australia has some 2½ times that of U. S. on that basis. Narrow gauge adopted on account of supposed cheapness of construction. Commission appointed 1920 recommends change to 4 ft. 8½ in. gauge. Rolling stock of 3 ft. 6 in. roads not to be changed but to be worn out on feeder roads. No more inside cylinder engines to be built. Outside valve gear to be adopted. Calculated maximum tractive effort of locomotives low, 20,000 to 36,000 lbs. Limited by strength of draft rigging. Brick arches and superheaters standard practice. Passenger cars generally like British. Some with passageways the length of train. No heating arrangements. Each compartment of sleeping cars has an upper and a lower berth.

Some new 3-berth compartment cars on 3 ft. 6 in. roads. Internal combustion cars being tried on light traffic lines in outlying sections. Cost of keeping spares and reserve equipment high. Abstract of paper by F. M. Whyte before N. Y. R. R. Club. *Railway and Locomotive Eng.*, 3-22, 2000 w. CHH.

Some Features in Safety Car Design. A good word is said for the rebuilt car. The double track safety is favored as to riding qualities and maintenance. There does not appear to be any reason why the one-man car operation with full safety control should not be used on inter-urban lines, particularly on branch lines where the traffic is not very heavy. Size of car to which safety control may be applied is entirely immaterial. It would be just as safe to operate with one-man car weighing 75,000 or 100,000 pounds as one weighing 16,000 pounds. H. CORDELL. *Electric Railway J.*, 4-1-22, 500 w. IG.

Railroad Welding Standards. Best and most practical methods in use today and are recommended as standard practices. Detailed instructions for foremen and welders as to preparation of material, treatment of each type of equipment (sheets, mud ring, fire door, frame, valve castings, air compressor steam head, air cylinder lugs, journal boxes, brake shaft, etc.) by gas or electric welding. J. M. CALMBACH. *Acetylene Jour.*, 4-22, 18 figures, 4000 w. APS.

Arc Welding in Ship Construction. Report of paper before Japanese Society of Shipbuilders. Trial of this process in converting a steam trawler into an oil lighter was successful. Next attempt was in building a steel self-floating caisson 460 ft. long. Details of both applications given with drawings. M. HARMISHI. *Welding Eng.*, 4-22, 3000 w. APS.

Aerial Transport Today and Tomorrow. The conclusion of a series on this interesting subject, this forming the appendix. It takes up technical or mechanical matters omitted in the body of the paper, such as fuels, carburetors, landing facilities in Britain and France, fuel supply stations in the two countries, and other pertinent topics. LT.-COL. W. A. BRISTOW. *Aerial Age Weekly*, 3-20-22, 2400 w. MAH.

State Regulation of Common Carriers. This is a compendium of the laws bearing upon the motor vehicle as a common carrier, and the heart of it is a large and comprehensive table giving the provision of the laws in all the States. This gives the State agency which controls, the application of the control, general powers of the State agency. Special or extra State taxes and other information. *Automotive Industries*, 3-30-22, 3600 w. and two-page table. MAH.

New Motor Derrick Lighter. Detailed description of the "Worthington," a new 333-ton harbor service vessel, propelled by the first of the new Worthington airless injection marine oil engines, just tested out on Delaware Bay, and Hudson and East Rivers. This vessel has shown splendid economy. *Motorship*, 4-22, 2700 w. MAH.

Ship Rudder Styles Changed for First Time

This new rudder is capable of stopping a ship within its own length and when set at a certain position is able to turn the ship about in a complete circle. Photo shows the rudder open, and gives a fair idea of its compactness and size.—(International)

Unemployment

(From page 995)

Missouri—Employment has increased 3% in St. Louis and unemployment is less in Kansas City, State officials said.

Oklahoma—Lessened unemployment is ascribed to increased demand for seasonal farm labor and to the revival of drilling in the oil fields which followed the spring rains.

Arkansas—The situation in Arkansas, while still acute, is slightly better than at any time since January 1, 1922, according to Thomas A. Wilson, State labor commissioner.

Texas—Labor conditions in Texas are improving, according to Joseph M. Myers, commissioner of the State bureau of labor statistics. The opening of agricultural pursuits this spring will take many of the unemployed from the cities, where the conditions are the worst at present, he said.

Colorado—Never before has there been so much construction work in Colorado, both of highways and buildings, as is contemplated here in the near future, said Deputy Labor Commissioner Carl de Lochte.

Idaho—The departure from the cities of seasonal workers and the release of the temporary jobs some of them held is expected to bring the labor market to normal and to end unemployment for most of the Idaho workmen who spent the winter without work.

Oregon—There has been a great increase in building operations. Unemployment in lumber and agriculture, the basic industries, is close to normal.

Utah—The industrial situation is improving rapidly, according to State officials and men connected with various industrial and agricultural enterprises.

Nevada—Work on farms, highways and mines is being resumed and is taking increasing numbers of men daily, according to State Labor Commissioner Ingram. About 1500 railroad workers are idle.

California—The total of unemployment in California is probably 7 to 10% less than at this time a year ago, according to Federal and State labor department officials. During the winter of 1921-22 there were more unemployed than in the previous winter, but unemployment is reported to be decreasing rapidly. Unemployment persists in shipping circles.

Washington—Unemployment in Washington has dropped from approximately 25,000 men and women out of work December 20, 1921, to less than 12,000 today, including 4000 miners, according to estimates made by H. P. Everest, Seattle, State supervisor of industrial relations, and W. C. Carpenter, Federal employment agent for the Pacific Northwest, with headquarters in Spokane.

Correct Seating Increases Output

"Correctly designed seating decreases unnecessary fatigue and leads to increased efficiency. It means greater production and lowered costs, therefore, representing actual dollars."—*Industrial Management*.

You can increase your stenographer's and all other workers' output and eliminate tiredness by installing the right chair. The Roneo Worker's Chair has every principle recognized by leading authorities as necessary to accomplish this. It will save its cost every month, and we will be glad to prove it to you by a thirty-day trial. Send the coupon.

----- RONEO COMPANY

117 Leonard Street, New York City

Please send us Roneo Chairs for thirty days' trial. We will check the increased production.

Alaska's Treasure Chest

(From page 999)

the cold weather. The warm weather is beginning in Alaska now, and it is probable that extensive drilling operations are now being started.

According to the United States Geologic Survey, there are 12,667 square miles of coal fields in Alaska. Their resources are estimated at 150,000,000,000 tons, about half of which is lignite of too low a grade for many important industrial uses. The coal actually mined, most of which comes from the Matanuska field, reached a total of 77,000 tons in 1918, and fell to 60,574 tons in 1919 and 61,111 tons in 1920.

The Navy Department, under a co-operative agreement with the Department of the Interior, is engaged in an extensive program of building, prospective and development work in the coal fields. Work has been started in the past few years on several new mines yielding good bituminous coal.

Millions in Fish

THE fisheries of Alaska are great but declining. The total investment in the fisheries of Alaska in 1920 was \$70,986,221, of which \$62,550,727, or approximately 88 percent, was invested in the salmon-canning industry. The 1919 total investment was greater than this by \$3,195,339. The total value of Alaska's fishery products in 1920 was \$41,492,124, a decrease of \$8,789,940 from the previous year. Besides salmon, the most important fishery products are halibut, herring, cod and whale oil.

One of the most picturesque industries of Alaska is the seal fishery. At one time the seal herd seemed threatened with extinction, but careful Government regulation (credit where credit is due!) has started it growing again. In 1912 the seal census showed a total of 215,738 head, and in 1920 it had increased to 552,718. A total of 26,486 skins were taken in 1920, 14,852 of which were sold at auction in St. Louis for \$1,708,071. Other furs taken in Alaska are fox, bear, beaver, hare, lynx, marten, mink, muskrat, otter, squirrel, wolf and wolverine. The herds of blue and white foxes maintained by the Government produced a total revenue of \$80,699 in the season of 1919-20.

There are two great national forests in Alaska, the Chugach, comprising 5,130,034 acres, and the Tongass, comprising 15,449,302 acres. They present enormous possibilities for the production of pulpwood, and the Forest Service is making strenuous efforts to develop the industry. The necessary water power for pulp mills is present. Rules have been formulated by the Forest Service which it considers favorable to the establishment of such enterprises, and fourteen areas of pulp timber tributary to as many power sites have been blocked out and mapped. This attempt at development is complicated by a quarrel between Secretary Fall of the Interior, who wants to get control of the forests into his department, and certain forestry interests, who want the jurisdiction to remain where it is. Quarrels of this sort are one variety of evil results arising from the division of governmental power in Alaska, and at the same time they are one of the influences which retard the unification of that power.

The Trade in Reindeer

ANOTHER resource of Alaska worth mentioning is the reindeer. Twelve hundred of these were imported by the Government between 1892 and 1902, and the herds have increased until they are now estimated at 216,000 head. Two-thirds of these belong to the natives and one-third to Lapps and whites. An attempt is being made to ship reindeer carcasses to the United States for food, and it is estimated that 2,000 were so shipped in 1921. They are used extensively for food in Alaska. To further supply the territorial need for foodstuffs extensive attempts are being made to foster agriculture.

These resources have been developed in spite of obstacles of confused Government supervision and lack of a good

colonial policy. The population of Alaska decreased 10,000 between 1910 and 1920, and the present white population is estimated at about 30,000—just about as many persons as attend a championship baseball game in New York. This shows how inadequate have been our attempts at development.

Woodrow Wilson said in his first message to Congress, delivered December 2, 1913:

A duty faces us with regard to Alaska which seems to me very pressing and very imperative; perhaps I should say a double duty, for it concerns both the political and the material development of the Territory. The people of Alaska should be given the full territorial form of government, and Alaska as a storehouse should be unlocked. One key to it is a system of railroads. These the Government should itself build and administer, and the ports and terminals it should itself control in the interest of all who wish to use them for the service and development of the country and its people.

But the construction of railroads is only the first step; is only thrusting in the key to the storehouse and throwing back the lock and opening the door. How the tempting resources of the country are to be exploited is another matter. . . . The resources in question must be used, but not destroyed or wasted; used, but not monopolized upon any narrow idea of individual rights as against the abiding interests of communities.

That was said nine years ago, but the politicians in Washington have not yet found time properly to perform the duty so pointed out. They are now too busy devising means of giving a bonus to the soldiers whom they expect to re-elect them next fall. And the enterprising business men of America are not sufficiently interested to prod them into action.

Government Regulation or Ownership?

THE coal strike puts an awkward problem before the makers of government policy. Here is an industry that is constantly giving trouble to the nation, and which, by all accounts, needs regulation of some sort. Yet government regulation of business has given anything but satisfaction in the past, and the present administration is definitely committed to a policy of "less government in business." What is to be done?

The House Committee on Labor has listened to the arguments of John L. Lewis, president of the United Mine Workers, in favor of government control of the mines. "The mine workers say that there now seems to be no hope except thorough nationalization," Mr. Lewis told the committee. "No remedy has been offered by the operators, and in default of any other remedy the mine workers seriously suggest that the government take over and operate the mines."

It is hardly likely that the union's desires will be met. But there has been serious talk of a compromise between the propositions of the miners and the operators, in the form of mild governmental regulation. It is suggested that a body similar to the Interstate Commerce Commission might exercise partial control over the industry. Under such supervision the coal production regions might be divided into zones and the output of the mines regulated.

Insurance for Printers

Group insurance for employees has been approved by the United Typothetae of America. In a recent interview, Secretary W. I. King of the group department of the Connecticut General expressed the opinion that group insurance in the past had been sold to individual employers who were somewhat ahead of other employers in the same industry, and who recognized the value of increased co-operation on the part of employees.

"Of recent date," says Mr. King, "this interest in group insurance has spread from the individual employer to groups of employers in the same industry and even to association of employers in the same town. . . . The general printing industry, as represented in the United Typothetae of America is interested as a whole in the subject of group insurance, and the individual typothetae associations in the various cities are discussing group insurance in their locality."

\$100,000,000 Plus

This sum represented the annual bill for labor turnover in just one field of industry recently, figuring its cost as low as \$50 per employee. The real cost was nearer \$100 per employee, raising the total to \$200,000,000 per annum in cold cash.

This was "hire and fire" cost in just one kind of industry. Multiply it by the total number of industries to suit yourself. You and your employees are paying your share of this absurd waste. Why not do your share to eliminate it by constructively regulating labor turnover in your own business by adequate appeals to the *mental attitude* of your employees?

*"The Worker's viewpoint is the
Most neglected Factor in Industry"*

Export-Import

(From page 1009)

time. Secretary of Commerce Hoover regards it as remarkable that our trade has held on. His recent bulletin says:

"On the basis of a pre-war comparison we find, as will be seen from the following table, compiled from official figures, that the foreign trade of the United States is nearer normal than the trade of the United Kingdom, France or Germany, which are our principal competitors. While the figures in the table are only approximately comparable, owing to the fluctuations in the price level, it is believed they are sufficiently correct to indicate the relative advantage of the United States in foreign trade.

Foreign Trade of the United States, United Kingdom, France and Germany before and after the War.

Countries	Imports		Ratio of 1921 to 1913	Exports		Ratio of 1921 to 1913
	1913	1921		1913	1921	
United States...	\$1,893,900	\$2,509,000	133	\$2,364,500	\$4,485,100	191
United Kingdom	3,741,048	4,182,713	112	3,089,353	3,118,686	101
France	1,625,317	1,755,633	108	1,327,882	1,606,870	121
*Germany				4,966,327	1,920,976	39
Total Trade						
						Ratio of 1921 to 1913
United States				\$4,258,400	\$6,994,100	164
United Kingdom				6,830,401	7,301,399	107
France				2,953,199	3,362,503	114
*Germany				4,966,327	1,920,976	39

All figures, except ratios, are given in thousands. *Figures estimated on an eight months' basis.

"If the trade of various countries were analyzed by commodities instead of values, they would still show somewhat the same proportion. In other words, the trade of the United States, even in times of great depression, is higher than our pre-war level. During the last few months there has been a

distinct revival in trade from the low point, and I am confident that we have little reason to accept the pessimistic view of our foreign trade taken by many students of the question."

Asiatic Market Steadily Growing

ACCORDING to an analysis made by the New York Times of the relative positions held by the grand divisions of the world with regard to the foreign commerce of the United States, Asia is the one division in which our exports have shown continuous increase. The table given below shows exports for the first seven months of the present fiscal year, last year and 1913:

Exports—Percentage

Division	1922	1921	1913
Europe	55	54	60
North America	24	25	25
South America	5	8	6
Asia	13	9	5
Oceania	2	2	3
Africa	1	2	1

Viewing the whole field in perspective, it is evident that Europe still outranks all of the other divisions put together and the exporters should bear this in mind in considering the importance of trade in the various localities.

With the Financiers

(From page 1003)

favorable than was anticipated, and that the underlying improvement in the railroad situation is a flat denial of the gloomy prognostications which were heard earlier in the year."

In this connection considerable interest attaches to an article by F. Lincoln Hutchins in *The Annalist* of May 16, in which Mr. Hutchins says that the success of the railroads is being seriously retarded by over-equipment. The fact that a railroad is spread out over a vast territory makes it easy, he points out, for executives to overlook the fact that equipment is lying idle a large part of the time.

"In the case of the railroads it is beginning to be seen that overequipment in heavier rolling stock and its concomitant requirement for increased investment in ways and structures has eaten into gross revenues to such an extent as to bring capital returns almost to a vanishing point," Mr. Hutchins says. Savings, he opines, may be effected by quicker time on the road, longer runs for locomotives, and the setting of a time limit upon the holding of a locomotive in a terminal.

Increasing Power of Poster Advertising

ACCORDING to Prof. John O. Simmons in *The Poster*, for May, poster advertising as an effective means of merchandising has little more than scratched the surface of its possibilities. This is the day of display—by word suggestion as well as by picture illustration. The attempt is being made to satisfy the apparent public craving "We've got to be shown to be sold."

Increased appeal of the poster through more careful analysis of the artistic makeup is given as one of the principal reasons why more advertisers have this year allotted a larger percentage of their annual advertising appropriations to poster campaigns.

German Wages

How would you like to hire German labor at the rate shown by the following table compiled by the National Union of Manufacturers of Great Britain? According to these figures an ounce of gold will buy an hour's work:

In the United States	17.22
In Great Britain	50.16
In Japan	95.60
In France	117.31
In Germany	201.66

Books for the Executive

The following are a few suggestions in the way of books which executives in the several divisions will find useful. But these are only a very few among the large number available. We shall be glad to answer inquiries concerning your needs and supply the books you want, at short notice. Write to our Book Department

Glass, Pottery and Jewelry

ELEMENTS OF GLASS AND GLASSMAKING, By B. F. Biser.

A treatise for the practical glassmaker, giving recipes and formulas for the manufacture of plain and colored glass. 140 pp. \$3.

THE POTTER'S CRAFT, By C. F. Binns.

The whole range of ceramic science is put at the disposal of practical workers in the studio in this book. 171 pp. \$2.

Hardware and Paints

PAINT TECHNOLOGY AND TESTS, By H. A. Gardner.

Valuable for its information on raw products, oils and thinners, the results of elaborate exposure tests and research work. 256 pp. \$4.

HOUSE PAINTING, GLAZING, PAPER HANGING AND WHITEWASHING, By A. H. Sabin.

This book gives the householder sound and safe practice in the manufacture and use of paints and varnishes. 143 pp. \$1.25.

Iron and Steel

PRINCIPLES OF IRON FOUNDED, By Richard Moldenke.

A book that has very definitely been a help to foundrymen in solving their problems. 517 pp. \$5.

COMPOSITION AND HEAT TREATMENT OF STEEL, By E. F. Lake.

A comprehensive book which carefully analyzes of those qualities required for greater strength, resistance to stresses and strains, etc. 252 pp. \$3.

AUTOGENOUS WELDING AND CUTTING, By Theodore Kautny.

A pocket book for the works engineer, welder and student. Authoritative translation of a widely known German work. 157 pp. \$1.25.

Leather

MODERN AMERICAN TANNING, By well-known tannery foremen, superintendents and chemists.

Volume 1 deals with such topics as Hides and Skins, Location and Construction of Tanneries, Rough, Welting and Card Leathers, Upholstery Leather, Sheepskins, Tannery Labor, etc. 292 pp. \$5.

Volume 2 contains articles on Tannery Equipment and Management, Leather Tanning, Chrome Tanning, Upper Leather and Glazed Kid, Splitting Leather and Splitting Machinery, etc. 570 pp. \$5.

MANUFACTURE OF LEATHER.

A comprehensive treatise on the subject, from an historical summary to the analysis of leather. 441 pp. \$6.

Lumber and Wood Products

SEASONING OF WOOD, By Joseph B. Wagner.

A treatise on the natural and artificial processes employed in the preparation of lumber for manufacture, with detailed explanations of its uses, characteristics and properties. 287 pp. \$4.

UTILIZATION OF WOOD WASTE, By Ernst Hubbard.

Treats of sawdust as fuel, distillation of wood for recovery of volatile products, manufacture of alcohol and sugar from sawdust, use of sawdust in manufacture of briquettes, explosives and gunpowder, etc. 248 pp., 51 illus. \$4.50.

Machinery

LIBRARY FOR MACHINISTS.

Six books on shop practice written by widely known authorities: Tuning and Boring; Planing and Milling; Advanced Grinding Practice; Automatic Screw Machines; Modern Drilling Practice; Electric Welding. Fully illustrated, total 1800 pp. \$14.

MACHINERY'S HANDBOOK.

For the Machine Designer, Foreman, Draftsman and Toolmaker: a comprehensive collection of data in this single volume. 426 pp. \$4.

MACHINE SHOP CATECHISM.

The editorial staff of the *American Machinist* has compiled this work from answers to over 1000 practical questions which have appeared in that journal. 221 pp. \$2.

AMERICAN MACHINIST GRINDING BOOK, By Colvin and Stanley.

A reference book giving full data on machines, wheels and methods. Of especial interest to purchasers of grinders, to operators and those responsible for results in the grinding department. 383 pp. \$4.

Metals and Metal Products

METALLURGICAL CALCULATIONS, By J. W. Richards.

Three volumes covering the basic principles of chemical calculations and their application to metallurgical problems. Volume 1, Chemical and Thermal Principles; Problems in Combustion. 238 pp. \$2.50.

Volume 2, Iron and Steel. 236 pp. \$2.50.

Volume 3, Non-Ferrous Metals. 197 pp. \$2.50.

PRINCIPLES OF METALLURGY, By C. H. Fulton.

Discussion of alloys, measurement of high temperatures, slags and mattes, etc. The first American work devoted to the fundamentals of this science. 544 pp. \$6.

Mining

HYDRAULIC AND PLACER MINING, By E. B. Wilson.

A complete treatise on the removing of earth by the power of streams of water. 425 pp. \$3.50.

THEORY AND PRACTICE OF ORE DRESSING, By E. S. Ward.

A complete work on the treatment of ores by concentration processes at metalliferous mines in western America. Text closely related and fully cross-referenced to wide range of valuable tables and working drawings. 426 pp. \$4.

Printing and Publishing

THE AMERICAN HANDBOOK OF PRINTING.

A valuable encyclopedia of all branches of printing in concise form. 300 pp., illus. \$2.70.

PRINTING FOR PROFIT, By Charles Francis.

A book on the management of a printing plant based on varied practical experience. 404 pp. \$3.

Book Department, INDUSTRIAL DIGEST

25 West 45th Street, New York City

INDUSTRIAL CALENDAR

Secretaries of Associations are invited to send us the dates of their conventions as early as possible so that their conventions may be properly listed below. When especially requested by Association Secretaries, we will send dates and other available notices concerning meetings of other associations.

- May 31-June 2. *Pacific Coast Electrical Association, Affiliated with N. E. L. A.*, Annual Meeting, Los Angeles, Cal.
- June 1-2. *American Wholesale Coal Association*, Detroit, Mich.
- June 5-7. *American Association of Engineers*, Annual Convention, Salt Lake City, Utah. (C. E. Drayer, Secretary, 905 State Bldg., Chicago.)
- June 5-7. *American Boiler Manufacturers Association*, Annual Meeting, Buckwood Inn, Shawnee-on-Delaware, Pa. (H. N. Covell, Secretary, 191 Dikeman St., Brooklyn, N. Y.)
- June 5-9. *International Association, Rotary Clubs*, Los Angeles, Cal. (C. R. Perry, Secretary, 910 Michigan Ave., Chicago, Ill.)
- June 5-9. *American Order of Steam Engineers Assn.*, Philadelphia, Pa. (Andrew Lauterbach, 4726 North Warnock St., Philadelphia, Pa.)
- June 5-9. *American Foundrymen's Association*, Exposition Park, Rochester, N. Y. (C. E. Hoyt, Secretary, Marquette Bldg., 140 South Dearborn St., Chicago, Ill.)
- June 6-8. *American Wholesale Coal Assn.*, Detroit, Mich. (G. H. Merryweather, Secretary, Union Fuel Bldg., Chicago, Ill.)
- June 6-8. *National Association of Master Plumbers*, Fortieth Convention, Detroit, Mich.
- June 6-9. *National Assn. of Credit Men*, Twenty-seventh Annual Convention, Indianapolis, Ind. (J. H. Tregoe, Secretary, 41 Park Row, New York.)
- June 7-8. *Pennsylvania Retail Coal Merchants' Association*, Trenton Armory, Trenton, N. J.
- June 7-9. *National Wholesale Grocers of U. S.*, Chicago, Ill. (M. L. Toulme, Secretary, 6 Harrison St., New York City.)
- June 11-15. *Associated Advertising Clubs of the World*, Milwaukee, Wis. (P. S. Florea, Secretary, 110 West 40th St., New York.)
- June 12-15. *National Association of Retail Credit Men*, Cleveland, O. (W. Reis, Chairman, 15 West 37th Street, New York City.)
- June 12-16. *National Fertilizer Association*, White Sulphur Springs, W. Va. (John D. Toll, Secretary, 1010 Arch St., Philadelphia.)
- June 13. *Music Publishers Association of U. S.*, New York City. (E. T. Paull, Secretary, 243 West 42d St., New York City.)
- June 13-15. *Illinois and Wisconsin Retail Coal Dealers Association*, Hotel Highland, Delavan Lake, Delavan, Wis.
- June 13-16. *Linen Supply Association of America*, Chicago, Ill. (F. H. Hartless, Secretary, 646 North Parkside Ave., Chicago, Ill.)
- June 14-16. *International Circulation Managers Association*, Indianapolis, Ind. (C. Eyster, Secretary, "Evening Star," Peoria, Ill.)
- June 14-21. *American Railway Association, Mechanical Division*, Atlantic City, N. J. (V. R. Hawthorne, Secretary, 431 South Dearborn St., Chicago, Ill.)
- June 18. *American Train Dispatchers' Association*, Chicago, Ill. (C. L. Darling, Secretary, 1310 Mallers Bldg., Chicago, Ill.)
- June 19-21. *American Railway Association, Purchases and Stores Division*, Atlantic City, N. J. (J. P. Murphy, New York Central Ry., Collinswood, Ohio.)
- June 19-23. *National Retail Hardware Association*, Hotel Sherman, Chicago, Ill. (Herbert P. Sheets, Secretary, Argos, Ind.)
- June 19-24. *National Association of Building Owners and Managers*, Bedford Springs, Pa. (H. G. Loomis, Secretary, Omaha National Bank Bldg., Omaha, Neb.)
- June 20-23. *Society for the Promotion of Engineering Education*, University of Pittsburgh; Annual Convention, University of Illinois.
- June 20-23. *National District Heating Assn.*, Cedar Point, Ohio. (D. L. Gaskill, Secretary, Greenville, Ohio.)
- June 20-23. *Lions International Convention*, Hot Springs, Ark. (Melvin Jones, Secretary, McCormick Bldg., Chicago, Ill.)
- June 21-22. *American Society of Civil Engineers*, Annual Convention, Portsmouth, N. H.
- June 22-23. *National Hardwood Lumber Association*, Congress Hotel, Chicago.
- June 26-July 1. *American Society for Testing Materials*, Chalfonte-Haddon Hall Hotel, Atlantic City, N. J. (C. L. Warwick, Secretary, 1315 Spruce St., Philadelphia.)
- June 28-29. *American Association of General Baggage Agents*, Minneapolis, Minn. (E. L. Duncan, 332 South Michigan Ave., Chicago, Ill.)
- July 4-7. *National Amateur Press Association*, New York City. (O. I. G. Martin, Secretary, 71 E. Lancaster St., Kitchener, Ont.)
- July 9-12. *International Association, Display Men*, Chicago, Ill. (L. A. Rogers, Secretary, John D. Mabley Co., Detroit, Mich.)
- July 10-15. *Export & Import Exposition*, Baltimore, Md. (A. E. MacKinnon, 405 Lexington Ave., New York.)
- July 16. *American Institute of Banking*, Portland, Ore. (R. W. Hill, Secretary, 5 Nassau St., New York.)

Foreign Events

- May 28-June 5. *Motor Show*, Hotel De Ville, Prague.
- May to November. *French Colonial Products*, Marseilles.
- June 15-Sept. 15. *Annual Exhibition of Ceramics and Glassware*, Dresden, Germany.
- July. *Fair*, Czechoslovakia.
- July. *Second Near East Sample Fair*, Bratislava, Czechoslovakia.
- July 1-24. *Aircraft Exhibition*, London (Olympia).
- July 9. *Universal Exhibition*, Buenos Aires, Argentina.
- July 24-29. *International Tobacco Trade Exhibition and Conference*, London, England.
- August. *Coupe Jacques Schneider* (Seaplane Speed Race), Naples, Italy.
- Aug. 6. *Gordon Bennett Balloon Race*, Geneva, Switzerland.
- Aug. 6-20. *Soaring and Gliding Competition*, Clermont-Ferrand, France.
- Aug. 9-24. *Soaring and Gliding Competition*, Gersfeld, Germany.

SEDGWICK

Fitting the Machine to Your Needs

OUR individual requirements are of utmost importance in the selection or construction of that particular Sedgwick lifting and lowering equipment which will best accomplish the desired result.

We therefore invite your confidence and co-operation, to the end that your Sedgwick outfit may be always a source of utmost satisfaction to you and pride to us.

During our 30 years of specialized experience in the manufacture of Hand Power Dumbwaiters, Elevators and Gravity Lifts, we have built outfits to meet almost every conceivable condition.

From all this accumulated data we can quickly and *without extra cost* furnish you with *exactly* the right outfit for your job.

Ask us what our experience would indicate as being the proper equipment for your lifting and lowering.

For lifting
and lowering—
SEDGWICK

In the home, as well as in industry, Sedgwick outfits have been in wide daily use for more than a quarter century. Sedgwick Hand Power Dumbwaiters and Invalid Elevators are of greatest convenience and perfect reliability.

SEDGWICK MACHINE WORKS

For 30 Years Manufacturers Exclusively of Hand Power and Gravity Lifting and Lowering Equipment

150 WEST 15TH STREET, DEPT. D, NEW YORK, N. Y.

Porta

SCOOP CONVEYORS

for

Economy Handling Coal

THE unique design, the sturdy construction, the completeness of the *Porta Scoop Conveyor* assures reliable performance and economical, long-time service to every owner.

This light-weight portable conveyor is a complete answer to conveying problems at thousands of plants and its first and operating cost is but a fraction of the cost of a more elaborate, but no more capable, conveying system.

And what is more, you do not have to make expensive alterations in order to install a Scoop Conveyor. It is built in different widths and lengths and it is almost certain that there is a standard size which would ideally fit your particular requirements. There is no installation cost.

Over 5,000 Scoop Conveyors are in daily use. Write for catalog No. 51 showing how they reduce handling costs.

June 10

25 Cents

Speeding Up Industry
With Rate Reductions

Using Us to Your Profit

We announce an advanced development in our plan of operation, as a result of years of careful study of industrial tendencies, and past methods, practice and philosophy.

We propose to specialize in analytical and consulting work, as staff advisors.

Our long experience in the management field has equipped our firm members and associates to serve industry in a personal way through the medium of the following services:

Examinations—Including assays, surveys, investigations, management appraisals and reports for managers, banks, receivers and stockholders, made from an impartial viewpoint covering profit-making possibilities and programs of betterments.

Counsel—Including regular weekly or monthly visits for a given period on a retained basis for purposes of consultation and assistance in the solution of management problems arising in the meantime, or a specialized counsel available for short periods to cover specific problems.

Staff Supervision—Including counsel and general direction of individuals already in the client's organization working on industrial betterments, or of individuals to be secured through our assistance and placed in the client's organization to carry out a betterment program as devised by us.

Installation work we will do, as conditions warrant, at the suggestion and under the control of the client, as arranged for on the basis of a most careful determination of what should be done and the time required. The cost of this will be less than is usually the case.

The principle behind the development of these services is that of bringing into coordination the **INTENSIVE** experience of a client's personnel, and the **EXTENSIVE** experience of our firm members and associates.

The advantages of the services as above described are—

No antagonism of client's personnel.
Most effective use of our experience
Low cost to client.
Insurance against disorganization.
Avoids forcing the work.
Credit goes to client's personnel.

Conduct of business remains in hands of client.
Time of principals devoted to client's problems.
More effective plans and programs.
Develops client's organization.

Have your Secretary write for our Blue Book No. 3, which fully describes the branches covered by these services. If you also advise us which service you are interested in, we will include a brief outline giving more detailed information.

NEW YORK

Why Pay \$45 For \$6 Worth of Iron?

Why pay \$1.50, instead of 2¼¢ a pound for about 286 pounds of superfluous iron in a steam trap? That is literally what you do when you purchase a cumbersome steam trap of the bucket or float type, with its array of troublesome floats, levers, valves, water gauges, bowls, and other unnecessary parts.

The Steam Trap Sarco does everything that the larger, heavier and more complicated traps do. Yet it has but one moving part and weighs about 6% as much.

STEAM TRAP SARCO

because of its simplicity and light weight, sells for about one-third the price of other makes.

A Sarco saves money in the purchase price as well as in installation cost, for it requires no platform building, no supports, no pit digging. Can be easily and quickly installed at any point on the line.

Let us send you a Sarco on 30 days' trial. If you are willing to part with it at the end of that time, send it back and the trial will cost you nothing.

Write for booklet F-9 and full information.

Hyatt bearing equipped Lakewood trailers that have been helping to reduce handling costs at this busy freight terminal since November, 1920.

Handling Costs at Cedar Hill Reduced by Hyatt Bearing Trailers

At the big Cedar Hill freight terminal of the New York, New Haven & Hartford Railroad, 320 Hyatt equipped trailers are doing their part in handling freight at the lowest cost per ton.

These Hyatt bearing trailers have been in service constantly since November, 1920, with no bearing replacements, and it is to be expected that the bearings will continue to give this fine service throughout the life of the trailers.

When these trailers have to be moved by hand in making up trains, or when pushing them into the cars, one man easily handles each truck, instead of the two men necessary on the few plain bearing trailers around the yard.

These easy running qualities are also an advantage when the trailers are pulled by tractors because storage battery strains are eliminated, noonday boosting of batteries is not necessary and each tractor can handle more trailers.

As Hyatt bearing trailers operate for three to four months on one application of lubricant, a real saving in material and labor is realized.

Reduce *your* handling costs to a minimum, specify that your manufacturer furnish you with Hyatt equipped trailers.

CAPITAL RELEASED FOR OTHER PURPOSES

through Production Program

THE AMERICAN TOOL WORKS OF CINCINNATI,
through Mr. A. E. Robinson, General Superintendent, says:

***Production
Control on
50,000 Parts***

"As we are manufacturing 60 different types and sizes of lathes, planers, shapers and radial drills, having nearly 50,000 parts, production control is imperative. In 1920 we employed L. V. ESTES INCORPORATED to help us cut down the physical effort required in following production, and reduce delays and interruptions in dispatching.

***Shop Work
Never
Disrupted***

"The Estes man installed a machine control board which enables us to load our machines intelligently, and check up on the work done. A new plan of routing our orders and a system of flow sheets showing the parts in process of manufacture make delays immediately apparent and easily corrected. In effecting these changes the work of the shop was never disrupted.

***Stock in Process
Cut Down and
Capital Released***

"Estes has cut down our stock in process, and so released capital for other purposes, by making up a production program in accordance with the actual and anticipated orders. By installing better guides and controls, he has reduced inventories of parts, relieved foremen and executives of details, and smoothed out the production flow. The very satisfactory savings effected will be greatly increased under normal conditions.

***Estes' Prestige
Aids in Securing
Employee Cooperation***

"The prestige of the Estes organization aids greatly in securing the cooperation of our executives and workers. Estes men appreciate the other man's viewpoint, are open-minded and can work harmoniously with any organization."

A PART OF OUR SERVICE is to send an engineer to your plant to examine conditions that exist and consult with you as to the value of changes that might be made. This service is without charge to you—just write us that you would like to have it.

The Business Weathervane

A Summary of Expert Opinion

"Business is going to be better in the fall, and prices are going to be higher." This is the consensus of opinion among those in a position to know.

* * *

The **Brookmire Economic Service** points out that on the whole activity during the month has continued on the upward trend. "Although some of the textile lines showed slight weakness, iron and steel increased its output, copper strengthened, building remained at its high level of activity and building materials were in heavy demand, car loadings increased, and general purchasing activity, as measured by bank debit figures, recorded a

fairly substantial gain. On balance from reports of widely varied fields the month witnessed an orderly, if not rapid, advance in general activity.

"As far as sectional activity was concerned, the eastern portion of the central group of States, due to the increasing production of iron and steel, reported a substantial gain in purchasing activity over the previous month. From the sales standpoint it is worth noting the rapidity with which the Southern States are renewing their buying. From present indications, they are leading the agricultural regions in their return to activity. The rapid and material increase in the gross earnings of railroads serving that territory and comparative purchasing figures tell of increasing buying pressure, especially in the eastern States of the group."

According to the monthly review of the **Federal Reserve Board**, "In appraising the manufacturing situation a distinction must be drawn between basic commodities and those of a more highly finished sort. The marked improvement in the case of iron and steel noted in business surveys of previous months has continued during May, unfilled orders increasing materially and ingot production being the greatest in any one month since November, 1920. The demand for iron and

steel products continues particularly strong in the case of automobiles and railway supplies. Much the same may be said with respect to copper and the other non-ferrous metals. The advances in the price of copper and the reduction in stocks which had previously occurred have been accompanied by a general reopening of mines and a corresponding increase in the demand for mine labor."

In the opinion of the **Harvard Economic Service**, "Recent weeks have witnessed a further expansion of industrial output. The adjusted index of the volume of manufacture is now approaching 100. Last summer it fluctuated around 75.

The steady upward movement of production during the intervening months has afforded one of the most solid bases for optimism, since the increase of output has been in response to a definite increase of demand. This stimulus is more and more manifest. It has recently shown itself in generally advancing wholesale commodity prices.

"Were it not for the labor difficulties which now prevail so widely a further increase of production during the next few weeks might be confidently predicted. As matters stand, the immediate prospect is somewhat uncertain. The protracted strike of the cotton mill workers in New England is interfering perceptibly with output in this trade. And the coal strike, though involving no serious curtailment of operations in other industries thus far, is apparently beginning to pinch. Unless substantial alleviation of these difficulties is effected soon, a retardation of the increase, or perhaps even a decline, in the volume of manufacture is to be expected."

(Newark Evening News)

"Up Together, Down Together."

The **United Business Service** believes that "In the most important item—food—it is evident that retail prices are now lower than they have been at any time since April, 1917, while wholesale prices were at their lowest about the middle of last summer, and their trend at present seems to be slightly upward. The result should be a lessening in the

(Turn to page 1168)

Ten Per Cent Lower

HIGH freight rates have long been a hindrance to a normal resumption of business. The Administration has urged the necessity of making large rate reductions on essential raw materials, such as coal, iron-ore and building materials and smaller reductions on less important commodities. The Interstate Commerce Commission, in handing down its decision announcing a 10 per cent horizontal rate reduction, believed that a uniform cut in freight rates would have a more stimulating effect on the country's business.

The reduction in rates, as stated by the press, might well be misunderstood. The commission states that where the increase in rates as of August 26, 1920, amounted to 40 per cent, the new rate must be only 26 per cent above the base used for the 40 per cent increase. That is to say, a 14 per cent decrease on the basis prevailing before the last increase—but since the present rate is 140 per cent on that basis, the decrease from current levels will be only 10 per cent. A similar reduction will give the same 10 per cent result from the present level in each of the territories.

Passenger and Pullman rates were not affected by the decision. There has been considerable discussion in the press on this point and opinion seems to be general that a passenger rate cut is sorely needed.

In those cases where voluntary reductions on specific commodities have already been made, those reductions will be considered as a part of the decrease now ordered. Naturally the railroads have already made voluntary reduction on those commodities where a rate cut would be most likely to increase the volume of shipments. Consequently, the most valuable reductions so far as business stimulation is concerned have already been made.

How It Affects the Roads

THE rate reduction is estimated to reduce the gross income of the roads by about \$450,000,000, annually. But previous reductions have already accounted for a reduction of approximately \$200,000,000, which means that the Interstate Commerce Commission's decision will force a further reduction of only \$250,000,000 annually. The rate reduction was followed almost immediately by the announcement of the Railroad Labor Board to the effect that wages of maintenance-of-way employees are to be cut on an average of 13.2 per cent. This will take \$48,000,000 a year from the pay-roll of the railroads and will

go far toward making the rate decision bearable from the standpoint of the railroad executives.

The Railroad Labor Board has indicated that further reductions for the other classes of railway employees are to follow shortly. The Interstate Commerce Commission's decree hinted that if further wage reductions were made, additional rate reductions would be in order. Wage cuts were not taken into consideration in determining the new rates which will go into effect on July 1, and many believe that the Railroad Labor Board's decision indicates further rate reductions in the Fall.

Railroad employees are not taking the cut supinely, and on June 6 announced a conference at Cincinnati to consider a plan of campaign and possibly a strike.

Traffic Increase

THE roads will benefit not only by the reduction in wages which has been granted, but also by an increase in traffic, which is certain to follow. That the outlook for rail stocks is favorable was indicated by a firmness on the publication of the rate reduction.

That general business will respond to the rate reduction is a foregone conclusion. Transportation costs are an important element in living costs. When wool is transported to the mill, when clothing is sent to the manufacturer, when the suit is sent to the jobber and then to the retailer, freight rates play a large part in the prices of everyday articles of clothing. Naturally, one effect will be to delay the purchase of raw material or at least the deliveries of stock until after the first of July. There is no ques-

tion, however, but that we are on the eve of steady price advances on practically all commodities, and it is possible that any saving in freight will be more than overbalanced by the higher prices later on.

Nearing the Danger Point

FOR nine weeks the coal strike has been dragging along with no settlement in sight. Our "April Fuel" strike may prove troublesome unless something is done quickly, and so the Government has called a conference of coal operators with Secretary of Labor Davis. Estimates place the amount of bituminous coal still in reserve at approximately 32,000,000 tons, but experience proves that in times of coal shortage whenever reserves get below 20,000,000 tons, prices start to climb and the famine is felt. This leaves a balance of some 12,000,000 tons before the consumer feels the pinch. The consumption of coal is now about 3,000,000 tons a week in excess of non-union production. This excess may be reduced

(Columbus Dispatch)
A Pendulum Must Swing Both Ways.

in Perspective

to 2,500,000 or 2,250,000 a week if the non-union mines increase in efficiency, as expected. So it is not difficult to determine that in another month manufacturers are going to have trouble in getting soft coal unless the strike is settled shortly.

In the meantime, Secretary Hoover has stepped into the breach with his announcement of a fair maximum price of \$3.50 a ton for bituminous coal at the mines in 80 per cent of the present production fields. Because of possible infringement of our peculiar anti-trust laws, Secretary Hoover did not ask the 500 producers, whose mines are still in operation, to agree among themselves as to a fair price but assumed all responsibility. When our Secretary of Commerce finds it necessary to request industrial leaders to overlook an antiquated act of legislation, it is in the opinion of many editors about time that the legislation be abolished.

Steel Production Increases

THE remarkable activity in the steel industry, especially as regards fabricated structural steel, is largely occasioned by the building boom. The contracts already awarded do not begin to equalize our shortage of industrial and residential buildings. The late lamented period of depression differed in one essential from all other similar periods—a shortage of dwelling houses. In the past, depressions have found us overbuilt—but today there is a shortage in practically every part of the country. The fact that contracts are still being awarded in large volumes is a very healthy indication because of the building industry's intimate contact with other industries. Take for

example, the lowly bathtub. Using the index number of 100, orders for bathtubs in December were 112, in January, 142, in February 152, as compared to 82, 65, and 71 respectively for the same three months last year. This same increase in activity is found in the glass industry, furniture industry, the electrical fixture industry, and many others.

More Mergers

THE so-called "six company" steel merger dwindled down to three when negotiations were completed—The Midvale Steel & Ordnance Co., the Republic Iron and Steel Co., and the Inland Steel Company. The new company, which will probably be called the North American Steel Corporation, may later absorb the Brier Hill Steel Co., and the Steel & Tube Company of America. Another important merger, that of the Selden Motor Truck Corporation and the Atlas Truck Corporation, has just been completed. It is reported that the consolidation, which will be known as the Industrial Motors Corporation, will attempt to do for the motor truck industry what the General Motors Corporation has accomplished in the pleasure car field.

Then there is the consolidation of independent coal properties, worth about \$40,000,000, in the Panhandle region of West Virginia. It is said that the surveys of the properties are almost complete and financial arrangements almost agreed upon. John A. Bell, chairman of the Carnegie Coal Company, is mentioned as one of the leaders of the merger operation.

(Kansas City Star)

The President Induces the Gentleman to Step Aside

AN expression of satisfaction arose from American business men when they heard that the Interstate Commerce Commission had ordered a 10 per cent horizontal reduction of railroad freight rates. The applause was not enthusiastic—no one seemed to think that the rate reduction would bring on an immediate boom—but it was virtually universal. Even the railroad executives failed to object seriously, perhaps because they knew a reduction of wages would follow the cut in rates. The general opinion seemed to be: "Every little bit helps, and business should be duly grateful for this slight boost toward prosperity."

A newspaper reporter in Philadelphia went the rounds of the important business men of his city to find out what they thought of the rate cut. The head of a firm of manufacturing chemists said it was "a very healthy sign of improvement in the times." "Everything in the building line will be aided," said the president of a contracting corporation. Local leaders in the steel industry said that the freight cut would furnish "the needed stimulant to make business better." The oil business, according to a leading Philadelphia representative of that trade, will receive no direct benefits but would "undoubtedly share in the general improvement that the rate cut would probably stimulate." Coal dealers told the reporter that if it were not for the strike they would expect "a marked improvement in the trade as a result of the rate slash." And so on.

The Greatest Beneficiaries

THE greatest benefit will, of course, be felt by the shippers and receivers of bulky commodities. A 10 per cent reduction in the cost of shipping a pair of shoes will not make a large hole in the total cost of the pair of shoes, but in the case of heavy building materials, coal and iron ore, the situation is quite different. The cost of transportation is a large item in the cost of these commodities, and a 10 per cent freight reduction is important.

The rate cut should reduce steel manufacturing costs by an average of at least \$1.25 a ton, according to the *Wall Street Journal*, which says:

"Saving will vary with different localities and in respect to different products. In some districts assembly costs of pig iron are around \$14 a ton, so that in these districts saving on iron alone would be \$1.40 a ton.

"Present assembly cost of pig iron in Pittsburgh district is \$10.48 a ton, which, with 10 per cent reduction, would drop to approximately \$9.43. In Cleveland and Buffalo districts assembly costs on iron are lower, about \$8 a ton, and reduction costs there would be about 80c a ton, while in Eastern districts assembly costs run to around \$14.

"Exact figures on assembly costs of finished steel are not available and vary materially with different mills. On the standard products such as bars, shapes and plates, it is generally estimated that these costs, in Pittsburgh district, are usually in neighborhood of \$12 to \$12.50 a ton, while on more highly finished products they would be increased. It takes about six tons of raw material, ore, coal and coke, limestone, etc., to produce one ton of steel.

"Delivery costs to consumers will also be lowered appreciably by freight rate cut. Freight on one ton (2000 pounds) of steel from Pittsburgh to New York is \$7.60. Under proposed new rates it would be only \$6.84.

"It is doubtful, however, whether consumers will get any direct benefit immediately from lower rates except on delivery charges. For one thing, steel prices are still low, little above cost of production. Further, if the 12-hour day should be eliminated, as seems likely in view of President Harding's request to trade's leaders, this would doubtless mean an increase in costs that might fully offset the saving in assembly charges due to lowered freight rates.

"Saving of \$1.25 a ton on steel assembly costs would, at current rate of output, mean an aggregate saving of at least \$32,000,000 annually to the steel industry."

The Effect on the Coal Trade

AUTHORITIES on the coal trade estimate that the new freight rates will mean a reduction on bituminous coal of about 34c a ton to Philadelphia from the Pennsylvania and Fairmont, W. Va., coal fields, about 50c to central Massachusetts by rail from the Pennsylvania fields, and about 28c from Pocahontas and New River mines to the piers at Hampton Roads. The immediate effect of the cut will be to delay the buying of coal until after July 1, when the decision of the I. C. C. will go into effect.

Those who calculate the effect of the rate cut should bear in mind that the 10 per cent reduction is applied to rates as of August 26, 1920, and that the railroads since that time have voluntarily reduced rates on various commodities. These reductions, excepting the 16½ per cent reduction on grain, grain products and hay, will be replaced by the 10 per cent cut just ordered. This means, of course, that the reduction from present rates will be less than 10 per cent in many instances.

The actual reduction from rates in force today will probably be about 6 per cent, in the opinion of a railroad expert of Washington. According to the correspondent of the *New York Times*, he reached this figure in this way:

"He estimated that on the basis of operating revenue of the carriers in 1921, the 10 per cent decrease provided for in the commission's order would represent a loss of \$450,000,000 in operating revenue. He stated that the loss of operating revenue on the same basis of calculation, because of readjustments and reductions made by order of the commission or

voluntarily by the carriers subsequent to August 26 and which are now in force, represented an annual loss in operating revenue of about \$200,000,000. This would leave \$250,000,000 annually as the additional loss in operating revenue to the railroads on the basis of 1921 business because of the commission's latest order. The order, therefore, he figured, would appear to represent an actual reduction from the rates in force today of perhaps 6 per cent."

In the opinion of Herbert Hoover, Secretary of Commerce, a rate reduction by commodities would have been of greater benefit to business than a horizontal decrease. Mr. Hoover urged before the committee that rates on some kinds of freight are low enough already, and on other kinds more than the average reduction might be required. But the commission, after considering the question in detail, concluded that a reduction by commodities was an impossible task at this time. Commissioners Lewis and Cox dissented. Mr. Lewis, in his opinion, went so far as to say that the 10 per cent horizontal reduction when spread over the entire freight traffic would prove an unjustified economic waste, and would have no perceptible influence in lowering costs of living or stimulating industry. Most observers, however, although they might grant that a reduction by commodities would be more desirable, seem to think that a horizontal cut is certainly better than nothing.

Why the Cut Was Made

BEFORE and after the promulgation of the decision by the I. C. C. came two events that throw light upon the rate cut and at the same time add to the difficulty of analyzing it. A few days before, the heads of the nation's important railway systems met President Harding at dinner and discussed rates. It was said a few days later at the White House, apparently at one of President Harding's informal conferences with newspaper correspondents, that "the railway leaders were adamant in their position that there can be no reduction in rates without a corresponding cut in wages." (The quotation is from a Washington correspondent of the *New York World*.) Then, a few days after the announcement of the rate cut, came a decision of the Railway Labor Board reducing the pay of 400,000 maintenance of way employees by 13.2 per cent. At the same time the board let it be known that it would shortly hand down decisions affecting the wages of

500,000 railway shopmen and 200,000 clerks, telegraphers, station employees and other minor groups.

President Harding's Role

THEORETICALLY there is no connection between the President's dinner and the rate cut, and between the rate cut and the wage cut. Yet there is a strong temptation to speculate about the actual relations of the three events. Did the President tell the railroad men at the dinner of the two forthcoming decisions? Did the railroad men accept the rate cut without protest because they knew there was a wage cut to follow?

The I. C. C. said in its rate-cut decision that previous wage reductions had not yet been counterbalanced by sufficient cuts in rates, and hinted that future wage cuts would be followed by further rate slashes. In other words, the commission's official position is that the present rate reduction has no relation to the present wage reductions.

The railroads certainly feel that there is a connection between the two. The commission, unofficially, must surely think so, too. It ruled that 5 3/4% of the aggregate value of railway property constitutes a fair return on the investment, and at the same time it cuts 10% off a schedule of rates which prevailed during a year when the railroads barely earned 3 1/3%. Surely the commissioners had wage reduction in mind as one of the means by which the roads could make up the deficiency.

Reduced Rates Mean Reduced Wages

THE railroad executives, at any rate, are thinking of wage reductions. The *Railway Age*, which is considered one of their mouthpieces, commented as follows on the rate cut:

"It is difficult to see how the railroads can do otherwise than accept the commission's decision to reduce rates. They should, however, make their assent of greatest value to themselves and the public. . . . They should certainly express themselves about the activities—or rather the lack of activity—of the Labor Board with reference to the shop wages decision."

Organs of general public opinion, too, connect the rate cut with the wage reductions. The *New York World* thinks, with some misgivings, that the roads will try to pass the entire rate reduction along to labor. It says:

(Turn to page 1058)

Where "deliver the goods" is the order of the day, this giant of transportation takes all blue ribbons. The engine in the middle is No. 5015 of the Erie, the greatest locomotive in the world, with 24 drive wheels and 416 tons weight. It earns its daily fuel by pushing heavy trains up mountain grades in the Susquehanna district in Pennsylvania. (E. Gallows)

Industry's Iron Horse

(Above) One pioneer iron horse was the De Witt Clinton here shown hitched to the first train that made regular runs in America. The engine was made at the West Point Foundry and made its first trip in August, 1831, from Albany to Schenectady, N. Y., in 13¼ hours.

American prosperity trailed behind these brave iron colts—the forerunners of our present breed of speed demons. When the lusty infant above first made itself heard it was the first full-sized locomotive run on a track in the United States, having startled the peaceful citizens at Honesdale, Pa., in 1829.

The lady above—the "Countess of Dufferin" made her blushing (blustering) debut in Canada in the early 80's. Incidentally she was the first engine on the Canadian Pacific R. R.

(Left) "Watch our smoke" is a saying that probably originated in '49, when old-timers saw this smoke-stack announcing the arrival of the pride of the Southern Pacific, the "S. P. No. 1."

Yesterday and Today

(Right) Breaking the world's carload lot record with a shipment of 100 freight cars bearing 500 automobiles from coast to coast. This is one of the "prosperity specials" that is speeding the country on to its new industrial era.

Some railroad employees are smiling these days. Engineers, firemen and conductors are unaffected by the wage cut announced by the Railroad Labor Board—perhaps because the Big Four Brotherhoods are so strongly unionized. This monster—hauling Erie freight—is the largest locomotive in the world. (© Galloway)

"The railroad executives may be of different minds on some other aspects of the 10 per cent rate reduction ordered by the Interstate Commerce Commission, but they seem to be of only one mind when it comes to placing the sacrifices supposed to be involved. Labor and not the roads should be made to take over this burden.

"It is true that railroad wages have already been reduced from the high war level by a larger percentage than freight rates from the same level are now to be reduced. But if President Harding or the Interstate Commerce Commission had thought that this much-belated rate reduction would be accepted by the roads as evening up the score they evidently have another guess coming. It is a new score rather which has been opened, according to the roads, and an equivalent wages reduction should immediately follow.

"We are sure that the roads in this attitude do not intend to manifest an ungrateful spirit toward the Administration in its efforts to exhibit cheaper transportation as a proud accomplishment for use in the coming Congressional elections. Nothing of the sort. They are in favor of cheaper transportation so long as it costs them nothing either in present growth of net returns or prospects of greater growth. On this basis they are perfectly willing to help out the Grand Old Party at the polls. But on this basis wages must come down another notch. What the shippers are to gain, labor and not the roads should lose."

New York's other Democratic morning paper, *The Times*, does not share *The World's* sympathy with railway labor. It says:

"Opinions differ whether the reduction of railway rates will increase or decrease earnings, but there is something like unanimity that it ought to be followed by a cut in wages. That is not the view of the Labor Board of the Interstate Commerce Commission. The first thought of the commission is that the rates should suffice to supply the country with adequate service. The Labor Board thinks that wages of a public utility are a prime matter of public concern, of humanity as well as economics, and that wages should not be lowered merely to make profits. That is general practice. Wages are

the first fixed charge, mechanics' liens ranking even ahead of mortgage interest or taxes. If either a public or a private concern cannot pay fair wages, it ought to stop running rather than keep alive on cut wages.

"On general principles, the transportation act should not be tinkered with until it has had a fair trial under something like normal conditions. The situation calls for peace and rest until the outlook is clearer. The next move is the Labor Board's. Its prudent course would be to make changes on considerations affecting labor alone. That is its duty under the transportation act as well as under general law and practice. The statute sets seven standards for the fixing of a fair wage. The first of them is: 'The scale of wages paid for similar kinds of work in other industries.' There is not a word in the statute about a 'living wage,' or a standard wage, or union wages. The railway workers have set up these and other extra-legal demands, on scales beyond the capacity of the industry to support. If the railways paid what the workers demand, there would result a deficit of a billion, or even more.

"Some railway wages are due for a reduction because they are out of line with those paid in other industries. That is less true of the train services than of the shop crafts. There are no comparable wages by which to try the train-service wages. They gained nothing by the "national agreement" under Government operation. Under it the wages of the unions affiliated with the Federation of Labor rose earlier and higher than those of the train services. The Labor Board has revised the "national agreement," and the railways may come to operate under the revision when it is possible to do so economically. If the board now fixes wages at the prevailing rates, and makes working conditions favorable to efficiency, it will be just to both labor and capital."

The railway unions began to hold conferences immediately after the announcement of the first wage cut. Just how much trouble may be expected from this source is problematical. Representatives of the railway executives express doubt that strikes will result. They say that public opinion is unfavorable to strikes at this time, and that the unions now have a poorer case than they had when the last railway wage cut was an-

nounced. At that time, representatives of the executives recall, the union chiefs were constrained to admit that they did not want to strike.

Moreover, only non-operating employees are expected to be involved in the wage cuts, for the present, at least. The Big Four Brotherhoods will not be asked to accept lower pay until the maintenance of way, shop and station employees have been disposed of. The reason for this is not only the strength of the organization of the Big Four, but the fact that the nature of the work they do makes their position extremely difficult to attack. The men who shovel cinders along the lines and drive rivets in the shops can be replaced, if they strike, by workers drawn from other industries, but the men who run the trains are irreplaceable. They can be trained only on railroads, and once they are trained the railroads cannot get along without them.

The commission did not feel that the rate reduction would work hardship on the roads unless a wage cut followed, for it was indicated that further reductions might follow, should a wage cut be decided upon. Commissioner Eastman said in this respect:

"We have no right to assume or to conclude that wages will be or ought to be reduced. Nevertheless, these wages, which constitute the chief factor in railroad operating expenses, are now on trial, and it is at least possible that they will be reduced. If they should be, we must either re-open our proceedings and make a new determination, to the confusion of industry, or the country must forego for a time so large a reduction in freight rates as would have been possible if we had postponed our decision.

"It is my best judgment that it would have been wiser and better if we had announced several weeks ago that our decision would be deferred until after the Labor Board had acted, not for the purpose of in any way prejudging the question of wages or of influencing the action of that body, but for the purpose of so timing our own action that we might be assured that the rates which we were prescribing would be the lowest possible under the law and the rates most likely to remain stable for some considerable period of time."

In making the rate cut the commissioner expected the loss in revenue to the roads to be offset by a considerable increase in traffic, and possibly by further operating economies. The increase in traffic is generally expected to come as a result of the general business revival. The railroad executives, as well as the public, expect it to come, although they insist that it will not be speeded by the rate reduction. In their

(© Chicago Tribune)

Perhaps This Will Rouse Him

1921, of 16,652 cars; in other words, for the first full week after the rate reduction, instead of the business being stimulated there was a decrease as compared with the average of nine weeks previous of 2,021 cars, or of about 12%.

"Nor, it will be noted, was this week ending April 8 exceptional, because for each one of the four individual weeks, which covers the period ending with May 6, the weekly loadings were even less than for the week ending April 8.

"On this showing it may fairly be stated that if this freight rate reduction had any effect at all upon the volume of the movement it was to serve to decrease it.

"It is also interesting in this connection to recall that under normal conditions the weekly April movement is heavier than the weekly February movement, but from this particular territory during 1921 the reverse condition obtained, although the freight rate reduction was in effect during April and not during February of that year.

"When the reduction as shown did not stimulate the movement of lumber it did cause the southwestern lines, under pressure from the yellow pine lumber mills located in that section, to subsequently reduce the rates on that class of lumber to interior points in Kansas, Nebraska and Iowa, meeting in a measure the competition which had been engendered by the reduction from the Far West."

In spite of this, the roads do expect an increase in traffic. They will attribute it to the general improvement in business conditions, and not to the rate cut. As long as it comes, it makes little difference to what it is due. And the general expectation is that it will come.

The employees' unions are expected to fight the cut, but no doubt have little real hope of success.

Passing of the Twelve-Hour Day

Working hours in the steel industry have steadily decreased since 1910—other industries also show improvement

DOES a shorter work-day increase efficiency? Is a workman able, because of the relief from fatigue, to produce as much in eight hours as in twelve? These questions, long under consideration by industrial leaders, are now of timely interest, both because President Harding, at his recent dinner with the captains of the steel trade, exacted a promise to abolish the 12-hour day wherever possible, and because labor unions are continuing their pressure for shorter hours in spite of the demand of industry for increased productivity per man.

At just about the time when President Harding was holding his conference with the iron masters, the International Labor Office of Washington made public the results of a questionnaire sent to the iron and steel works of foreign countries, showing that three shifts of eight hours each are much more costly than two shifts of 12. The questionnaire, which consisted of 13 questions, with sub-divisions, was sent out by the headquarters of the International Labor Office at Geneva, Switzerland. It was printed in five languages, and was sent to governments, employers' associations and workers' organizations of 54 nations. Replies, so far, have been received from 15 countries.

The responses, as summarized in *Iron Age*, show that nearly all the foreign steel-producing countries are now operating on either a three-shift or an eight-hour day, or both, and that in consequence the number of workers has been increased by 30 to 50 per cent, with a corresponding increase in labor costs.

"Almost without exception," says the summary of the report, "it has been the policy of the iron and steel manufacturers to pay the same wages for eight-hour work as was paid heretofore for 12-hour work. *There has been no appreciable increase in output, and in certain cases the production actually has decreased both as to total and as to each worker.* This statement is based on reports from foreign governments and employers, and while workers' organizations do not always report similar conditions, many of them do. The result so far has been quite surprising, in view of the claims of organized workers in all lands that reduced hours would increase the efficiency of workers and their individual output, and at the same time would mean little or no difference in cost of production."

The change from the two-shift to the three-shift day began

in isolated instances as long ago as 1912, and in most countries in 1917. Since then it has been progressive. Some of the replies to the questionnaire indicate that the shorter work-day is the result of political and economic disturbances and other conditions arising from the war, and that possibly it is too early to say definitely what the change will mean.

The 12-Hour Day in Other Countries

THESE nations replied to the questionnaire: Austria, Belgium, Canada, Czecho-Slovakia, Finland, Germany, Great Britain, India, Italy, Jugo-Slavia, Poland, Roumania, Spain, Sweden and Switzerland. This list includes all the important steel-producing countries except France.

The replies from Germany and Austria are the most complete. The change in these countries was made at the demand of the workers, whose dissatisfaction with long hours became most marked after the war. These unions speak well of the change, but the employers condemn it emphatically. The employers say that the shorter day has been accompanied by higher costs, inferior workmanship and lowered morale. The government reports take a middle course. In many countries the three-shift day has been established by law, and in other nations it is the result of a voluntary agreement between the unions and the employers. In some instances the employers took the initiative in establishing it.

In Austria the three-shift day entirely supplanted the two-shift day by an act of December 19, 1918, which became effective on January 8, 1919. The change was the result of an appeal by the workers immediately after the Revolution. In Belgium the three-shift day, which has been in force since the beginning of 1920, was the result of pressure by the workers. At the same time the eight-hour day was established in some of Belgium's rolling mills where the work is not continuous. In Canada, out of 15 firms operating blast furnaces, open hearth furnaces, electric furnaces and rolling mills, three are partly on the three-shift system now, and one adopted the three-shift day in 1917 but later returned to the old scheme. The remaining works are on a two-shift basis and do not expect to change. The changes in Canada were made voluntarily by the employers.

Most of the steel works in Czecho-Slovakia operate in three shifts when they are running at full capacity, but today.

Comparison of Working Hours in Steel Mills Between 1910 and 1920 Shows

because of the business depression, only a small proportion are on that basis. One shift is employed in most metal factories engaged in the later processes of manufacture. The three-shift system, however, has been adopted in the tube and plate mills and in enameling and galvanizing works. This system was introduced on December 1, 1918, at the demand of the workers when the old regime collapsed.

In Finland the three-shift system was introduced early in 1918 upon the initiative of employers after the passage of an eight-hour law. In Germany three shifts had been in general use since the end of 1918 or the beginning of 1919 in all plants in which uninterrupted work is necessary. The three-shift system in Great Britain, which has displaced the two-shift system in all but a few isolated cases, became effective early in 1919 as the result of a trade-union agreement.

The eight-hour day is general throughout Italy, three shifts being used in processes which require continuous work. In many factories the change took place in 1919, and in others it was delayed until 1920. It was due chiefly to the activity of workers' organizations.

The Movement in the U. S.

IN the United States the shorter hour movement has been going on for a longer period of years. In 1910 the 12-hour day was general throughout the steel industry of this country, except in sheet and tin-plate mills, puddling mills and among the highly-skilled employees working on bessemer converters. The accompanying illustrations show the extent to which the 12-hour day has been replacing shorter and more humane working hours.

These statistics reveal that the policy of leaders in the steel trade has been to reduce the hours of labor gradually, and in such a manner as to produce a minimum of disturbance in the industry. Their acceptance of President Harding's proposal shows their willingness to continue this policy.

In other trades the movement toward a shorter work-day has proceeded more rapidly. This is especially true, of course, of industries in which labor is highly organized.

An investigation of unemployment in New York State by the State Department of Labor uncovered, incidentally, some interesting information on standard working hours. The eight-hour day, it was discovered, is the standard for the majority of workers in the State.

"In New York City three-quarters of the men and more than three-quarters of the women are employed on an eight-hour basis," says the report by Dr. Patten, chief statistician for the department. "Twenty-five per cent of both men and women have a standard 44-hour week.

"Up-State only 54 per cent of the men work an eight-hour day—usually a 44-hour week. About half the women work an eight-hour day, and half work a nine-hour day, which is the legal limit for women. Longer hours are worked by women than by men in some industries, due, obviously, not to the working of a longer day by women than by men in the

same trade, but to the circumstance that the women predominate in the largely unorganized trades where hours are longer."

Working Hours in New York

THE influence of the clothing, fur, shoe and printing trades is responsible for the shorter hours in New York City, the report continues. In these industries the 44-hour week is general. The unions, generally speaking, are stronger in the city than in the up-State districts. The greater amount of time consumed in transportation to and from work is also conducive to shorter hours. The food, beverages and tobacco industries form the only large group in the city to report a working day of nine hours or longer.

Longer hours in New York State were chiefly in the stone, clay and glass, wood-manufacturing, textile and food products works. The longer hours worked by women up-State are due to the greater representation in the clothing trade, of the men's shirts and furnishings factories, which work a nine-hour day. The industries in which the eight-hour day predominates up-State are the Chemical industry, the shoe trade, pulp and paper manufacturing and printing.

"In 1913," says the report, "the nine-hour day was the prevailing working day in factories of New York State. In New York City about one-half the workers were employed nine hours a day, but more than one-third were on an eight-hour day. Up-State more than half the wage earners were on a nine-hour day, but most of the remainder were working ten hours a day or more.

"As in 1921, the leaders in the shorter working day were the printing and the clothing trades. They were on a 48- or 54-hour week, however.

"The longest working hours in 1913 were in the stone, clay and glass, the wood-working and the food products industries, as at present, and in the pulp and paper industry. The latter reported the greatest reduction in working hours of any industry—from more than 63 in 1913 to 48 a week in 1921. The reduction is the result of the change in that industry from two-shift to three-shift operation, which changed the working day from 11, 12 or 13 hours in the continuous processes to eight hours.

"In general, the primary manufacturing industries, those in the rural districts or the one-industry towns, and those in which women are in a majority, have longer hours. The industries producing highly manufactured products, those requiring skilled men, those located in the cities and those where unions are strongest, work shorter hours.

"About 60 per cent of the employees in the metals and machinery industry work an eight-hour day. Very few work a 44-hour week. In the ship-building industry almost all of the employees work an eight-hour day. The jewelry, automobile, machinery and electrical apparatus and railway equipment industries have about three-quarters of their employees on an eight-hour basis. In the jewelry industry in New York City a 44-hour week is general. The longest hours in any industry are worked in the pig-iron and rolling mills, where all the employees up-State work more than 54 hours a week. In the instruments and appliances industries less than half the men, but 60 per cent of the women work a nine-hour day."

Trend from 12-Hour to 8-Hour Day. Relative Heights of Figures Used as Basis

The farmer feels the result of business depression as well as the manufacturer, and should co-operate in the effort to keep industrial activity on a normal basis. These great grain store houses on the Great Lakes afford one means of properly coordinating agricultural and industrial life.

How Will Prices Act Next Fall?

Conditions are ripe for a rise in practically all commodities, though it may be only temporary.

FUNDAMENTAL conditions indicate that prices of manufactured goods will rise substantially next Fall. Prophecies such as this are dangerous, for economics today is far from an exact science. *THE INDUSTRIAL DIGEST*, however, feels that the situation today justifies the prediction of a general upward movement in commodity prices. No pronounced rise is to be expected during the Summer, for conditions are not quite ripe, and the Summer is an off season in many industries. In the Fall, therefore, the upturn should come, if nothing unfavorable happens in the meanwhile.

It remains to be seen whether this will be a major turn of the economic tide, the forerunner of a long period of rising prices, or simply a temporary reaction. An influential school of economists believes that the general trend of prices will be downward, or stationary for a number of years. They point to the period after the Civil War, when prices continued to drop until the 1890s, and they say that the present post-war period presents analogous conditions.

This opinion may be correct, and yet the upturn next Fall may still take place. If the major trend of prices is still downward, such an upturn will be a mere temporary reaction, and after it has run its course the downward movement will be resumed. The reaction, though temporary, would nevertheless be real, and business men will not regret having been prepared for it.

But the economists who look back to the 19th century and find there a precedent for a continued fall in prices are in the minority. Most of the students of business conditions think that prices have fallen just about far enough, and that there is a good chance for the upturn to be a major movement. *The Harvard Economic Service*, whose predictions are based upon statistics analyzed by men of the highest reputation, heralded a major upward swing. It refuses to permit a temporary decline to discourage it. In one of its late May reports it says:

"The very slight decline of business in April is to be interpreted as a temporary halt in improvement and a consolidation of the substantial gains made in the two months preceding. Such movements of business are usual during periods of recovery. In the present instance, as in former cases, the fundamental conditions making for business improvement remain. The [upward] course of speculation since last summer . . . and the decline of money rates in recent months . . . indicate clearly that the slight recession of business in April should be regarded merely as a pause in a major upward swing."

This service believes that an upward movement in speculation is an almost certain precursor of a similar movement in business. In this connection it is well to remember that the New York Stock Exchange, after a period of sluggishness, resumed a considerable degree of activity in the closing days of May.

Continuing to explain the temporary drop in its index of business conditions, the *Harvard Economic Service* says:

"Bank clearings outside of New York City, which with Bradstreet's index of wholesale commodity prices form the basis of our business curve, decreased during April more than the usual seasonal amount. This decline was sufficient to overcome a substantial rise in prices, and was responsible for the slight decline in the business curve. Although the decrease in clearings was widespread, it is evident that New England, New York, the Middle West and the Pacific Coast showed as favorable returns in April as is usual in comparison with March; while the Middle Atlantic region south of New York, the South, and the Southwest showed returns much less favorable.

"The cause of the decline is to be found partly in the coal strike, as is shown both by the large losses sustained by Pittsburgh and Denver and by the fact that the Middle Atlantic States, when allowance is made for the usual seasonal movement, show the most substantial decrease of any section. A second cause, of predominant importance in many regions of the South and West, is to be found in the generally unfavorable weather conditions during April, which resulted in floods and impassable roads in many parts of the country."

In other words, the decline is due to seasonal and temporary conditions. It is a drop in activity, not in prices, and conditions in general are favorable to an upturn.

One of the most important prerequisites to an upward movement is the restoration of public buying power. There are indications that this is near at hand. The prices of farm products, except garden truck and dairy products, have been slowly rising for some months, and reports from the agricultural sections have it that the farmer feels somewhat improved. In the month of April Dun's index number of wholesale quotations showed an advance of 5.5% in breadstuffs, due chiefly to the enhanced cost of the leading cereals. Meats also rose slightly. The total increase for all foods was 1.4%, a recession in dairy and garden articles holding the total down. Breadstuffs reached the low point on November 1, when they touched an index of 22.808. Their present index is 27.558. Since this classification includes some of the principal farm products of the country, this is a favorable indication.

After the prices of farm products, the chief determinants of buying power are the wages and steadiness of employment of labor. Unemployment, except in the strike districts, is said to be considerably improved. Accurate figures are hard to get, and even the most accurate obtainable are neither up-to-date nor reliable; but certainly complaints of suffering from unemployment are less vociferous than they were a few months ago.

It seems likely, however, that wages will decline no further. Labor in most industries is liquidated about as far as it will go. A notable exception is the railroad industry, where a proposed lowering of wages carries with it the danger of trouble, but it is to be confidently hoped that the reductions will be carried into effect and the disturbances all over by Fall. Most other industries have already succeeded in effecting wage cuts beyond which further reductions seem impossible.

Export Trade a Barometer

NOT the least hopeful sign is the increased export trade. This business touched bottom in March, and has been slowly climbing ever since. The proposed high tariff, if passed, may be expected to check this movement; but a substantial sentiment for the modification of the tariff is arising throughout the country, and may result in beneficial changes before the bill is placed before President Harding. Moreover, the effect of the tariff upon exports is indirect and probably will not have time to take effect until after the fall upturn has come.

Wholesalers and retailers throughout the country with small stocks of goods on hand have refrained from extensive buying because of a fear that prices would fall still further. They are still buying cautiously. But by next fall the time will be right for a change in their mental attitude. With the first indication of a rise in prices, there will probably be

Comparative Price Levels in Principal Countries, 1913-1922 (1913=100).—(*The Magazine of Wall Street.*)

a rush to lay in a supply of goods for the uphill period.

The re-entrance of the railroads into the purchasing field, a steady increase in automobile manufacture and the general improvement in business all over the country in mechanical lines, make it likely that enough workers will be employed in the large cities to maintain a steady purchasing power.

Strikes, too, will have an effect not altogether unfavorable. The coal strike will have the effect of stiffening fuel prices. The building

trades disputes all over the country are adding to the cost of construction and the price of houses. The textile strike will certainly have the effect of holding up the prices of some kinds of clothing.

The Favorable Factors

THESE influences are already making their force felt. The *Harvard Economic Service*, which believes that the most favorable factor in the present situation is the broadening of the upward swing of prices, says:

"The number of commodities which show increases has expanded greatly. Dun's index of price movements for May 13 showed 76 advances—the highest number recorded since the beginning of the upswing of commodity prices—and 24 declines; the week before, advances numbered 59, and declines 18. Advances predominated generally in April, and declines in March. Of the articles making up our ten-commodity price index of cycles, cottonseed oil, coke, pig zinc, pig iron, bar iron, hides (corrected for seasonal variation), sheetings and worsted yarns were higher on May 1 than on April 1; print cloths were the same, and mess pork lower. The index, with the omission of coke because of the disturbed condition of the market, stood at 56.6 on May 1, relative to 1919 as 100, and was thus 14% above the low point of August, 1921, and at the highest level reached since that date. The textile fibers have generally advanced in price. Spot cotton on the New York market went above 20 cents per pound for middling upland on four days during the first two weeks of May. This is the highest level reached since the first part of October. Wool likewise has risen, and there is said to be considerable speculative buying. The new clip in the West is selling rapidly. Raw silk rose from \$0.10 per pound on April 7 to \$0.90 on May 12. Burlap prices are rising, and there is a strong demand, due to increasing consumption. The American Woolen Co. increased the prices of its woolen goods during April, and more recently has advanced its worsted goods."

So it seems that a price upturn is starting, and may be expected to get into its full stride by Fall. Whether it is a temporary reaction or a major movement matters little.

If business takes the upturn quietly and without undue speculation and inflation, its effect will doubtless be beneficial. But not all price increases are beneficial, and there is a danger that the upturn may be turned into another bubble boom. The warning is sounded and the situation admirably stated by William O. Scroggs in *The New York Evening Post*, as follows:

"If business men were thoroughly canvassed it is probable that a large majority of them would be found to look upon high price levels as desirable and that a large number would

(Turn to page 1108)

No Monopoly In Steel Merger

THE need for economy in the steel industry, not the desire for monopoly, appears to be the real reason for the steel merger. At present the production is in the hands of greatly diversified interests. Even if the merger goes through, the output would not be controlled by two companies alone, as the opponents of the consolidation contend. According to *Iron Age*, "The United States Steel Corporation and all the important independent companies have a total of 79% of the country's capacity. The remaining 21% is distributed among 50 companies, 30 of which have annual capacities ranging from 100,000 to 700,000 tons. It is estimated that the capacity which the (then) proposed six-company merger would have, added to that of the Steel Corporation, would total only about 16% of the total capacity of the steel companies."

Perhaps the greatest benefit to be derived from the consolidation would be the lowering of delivery costs. Shipments could be made from the nearest plant to the point of delivery so that freight charges would be materially reduced.

Since the war, bond issues have been increasing throughout the steel industry and heavy deficits have been the rule. Unless some way is found of reducing the overhead costs, there is little prospect of either profits for the producer or cheaper steel for the general public.

The need for more efficient production methods will be realized when the present demand for steel is taken into consideration. There is reported to be heavy placing of orders for plates, shapes, etc., against freight-car orders and fabri-

cated steel jobs that have been under negotiation for some time, while there is heavy new buying by the automobile industry, which is running at a higher rate than was anticipated. The Department of Commerce reports the production in April of 196,412 passenger automobiles and 21,944 trucks. May production is running a trifle heavier.

Passenger automobiles, trucks, accessories and equipment are probably accounting for about 150,000 tons of finished rolled steel turned out in this country each month.

The Largest Chain Ever Made

The anchor chain on the liner *Majestic*, the world's largest ship. The links are 12 x 20 inches across, each weighing 400 pounds. In the center is the big winch on which the huge chain is wound.—(© Galloway.)

"Buying for a Bust"

"LOOKOUT for Jones—don't sell him on anything but a cash basis—they say he's buying for a bust!" Have you ever overheard a remark like that—and wondered what "buying for a bust" meant?

Well, this form of illicit failure became rather popular as a result of the late lamented (!) depression. The ease with which one could acquire goods by credit tempted many a merchant to expand his purchases far beyond the normal requirements of his business with the deliberate intention of first liquidating his surplus stocks at low prices and then going through bankruptcy proceedings on the best possible terms.

The reason for overbuying on the part of the merchant who plans a failure is evident, according to John L. Redmond, writing in the New York Credit Men's Association bulletin. The debtor wishes either to speedily convert the goods into cash to be secreted, or he will account for the merchandise purchased just before the failure, hoping thereby to divert investigation from other irregularities. It also enables him, in case of necessity, to offer a fair settlement to creditors at no loss to himself.

Fortunately, however, nearly every branch of industry has

its special agencies that have as subscribers a large percentage of houses in the trades that such agencies are designed to serve. A wide-awake credit department will note any increased size of orders and will inquire of the agency as to the present standing of the purchaser. In the case of a first order it will be delayed until proper credit information can be obtained. By such precautions credit agencies can be made aware that a purchaser is increasing orders with his regular sources of supply, and perhaps endeavoring to open new accounts. Interested subscribers of the agency are notified to hold up orders, while the agency calls on the purchaser for a statement of his affairs with an explanation of the number of new accounts being opened.

Once the presumption of overbuying is established, there should be no hesitation to call at the debtor's place of business with a demand for further information. If the debtor's replies are evasive his larger creditors should be consulted. It is the duty of the business community, particularly the duty of credit men, first to aid the honest debtor regain his standing, and, then to drive fraudulent debtors out of business.

Why Workers Like Daylight Saving

Better work, less spoilage, larger piece-work earnings, lessened eye-strain and more time for recreation under the new policy

THE next time you miss a train on account of a misunderstanding as to "standard time, which is one hour earlier than time used in this timetable," just remember how many good points this much-discussed innovation has to its credit. Listen to one of the factory workers in Paterson, N. J., tell you why he voted for daylight saving in the recent poll conducted by the manufacturers to ascertain whether the new schedule was popular with their employees.

"All day long," said this man, "I work with silk—not the kind you're used to seeing, but silk in its raw state, thousands and thousands of flying and whirling 'ends' that twist and break even when handled by an experienced man. And in the summer time, with the sudden changes in the weather we have around here, there is usually more trouble in beaming the warps from the machines, and more smashing of threads in the looms, than in the cooler weather. But when you get an early morning start and know that the greater part of your day's work is going to be finished before noon, it makes a difference. Things seem to go better. Then you can count on having time enough at night, too, for working in the garden, or for a ball game. It gives you a chance to look forward to the end of the day. We like it better than the old way."

Another reason why textile workers are so much in favor of daylight saving was given by a girl weaver, an expert worker on one of the huge Jacquard looms:

"I make more money since they started using daylight saving in our shop. We're paid by the yard, you know. Well, now we finish earlier in the day and it seems that I get more yards woven in eight hours than I used to. I suppose it's because I feel fresher and don't get tired so quickly."

This increased efficiency is also noticeable in other trades. In many cases productivity is increased because greater progress can be made by daylight than by artificial light. And in seasonal occupations a greater amount of work is accomplished than was the case under the old system. In the building industry, for example, where weather conditions play such an important part, the advantage of starting work early in the day is obvious.

Another important effect of daylight saving is the fact that it encourages city workers to live at some distance from their place of employment. Under the old schedule of working hours, the man who lived in the suburbs spent most of his spare daylight hours commuting. The morning was usually haunted by a fear of missing the train, and in the evening after his return from the city, darkness came so quickly that he soon became convinced that the so-called joys of suburban life existed only in the minds of people who had never tried it.

"Gardening was supposed to be one of the great attractions," said one of these disillusioned suburbanites, "but you can't carry it on very successfully by arc-light. With daylight

saving, though, it's different. It's worth while to get out in the country now, and I've made up my mind not to sell the place after all."

Daylight Saving Saves Eyes

THE diminished use of artificial light also has a beneficial effect upon the workers in factories where the work involves constant eye-strain. In all modern buildings skylights are employed whenever possible so that the maximum amount of daylight may be secured, and in many factories an effort is made to have electric light simulate daylight as nearly as possible by means of indirect lighting. But the best electric lighting system is not to be compared with daylight. And in some cases improper or insufficient lighting is said to result in inferior workmanship, damage to the equipment or machine, and sometimes even injury to the operator.

That daylight saving should be of especial interest to the people living in the cities and countries in the northern portion of the temperate zone is indicated by the accompanying diagram, showing the increasing number of daylight hours during the summer months for the latitudes farther north, as compared with the Southern latitudes, and the corresponding shortness of daylight during the Northern winter. This diagram is based on what is called "mean solar time," as the interval of time between the two successive noons constituting the solar day

Hours of sunlight and darkness along the 42nd parallel, north latitude, which passes near Salt Lake City, Omaha, Chicago, Cleveland and Boston; and in Europe, near Bordeaux and Venice. Duration of winter day, 9 hours, and of summer day, 15 hours.—(Prepared by U. S. Weather Bureau and Published in *Heating & Ventilating Magazine*.)

is not entirely uniform in length.

According to the recent census about half the population of the United States lives in the 75th meridian zone. Approximately 85 per cent of the persons employed in that zone are engaged in industrial, commercial, financial and professional pursuits—from which it would appear that working time should be adjusted to the daylight hours.

The *Heating & Ventilating Magazine* points out that the advancement of the clock half an hour in the latitude of 42° would bring the working day in winter between the sunlight hours of 7 a.m. and 4 p.m. In the latitude of 54° it would have to be advanced 1½ hours to effect the same purpose.

It is believed that the permanent advancement of time one hour in each zone of time, 75th, 90th, etc., would solve the daylight saving problem and increase the efficiency of workers in those sections where it is not now in operation.

Spain Buying U. S. Products

A REVIVING interest in American automobiles, food products and mining machinery is reported from Spain. The corn market also exhibits an increased demand for American products. The total imports of corn in February amounted to 24,000 tons, of which 4600 tons were American exports, while in March, out of a total of 13,000 tons, 5000 tons were from American sources.

Why We Need Export Trade

Exports form a marginal market that stabilizes prices and absorbs surplus of manufactures

HOW important is our foreign trade to the manufacturers of the United States? Can we get along without doing much of an export and import business, or is it essential to our prosperity that we take part extensively in the commerce of the world?

The question is pertinent now, because the United States Senate is considering a tariff bill which, by placing high duties on imports all along the line, will curtail America's foreign trade. By restricting imports the bill will also restrict exports, for foreign trade must work both ways.

Manufacturers who favor this tariff bill are inclined to think that our foreign trade is not of great importance. Let us keep out foreign-made goods, they say, and let us sell our own goods to our own people, thus keeping our prosperity to ourselves. Under the best possible circumstances, they say, American manufacturers ship only a small fraction of their products abroad, and it would be worth while to sacrifice this insignificant trade if we can at the same time shut out foreign competition in the home market. Other authorities, including many manufacturers, believe that this reasoning is shortsighted. They contend that America's export trade is highly necessary to her prosperity.

The President of the National Bank of Commerce of New York, speaking recently at a convention in Philadelphia, warned his auditors not to give weight to the argument that foreign trade is unimportant because it represents only 15 or

20% of the total trade of the nation.

"The difference between normal business conditions and depression is no more than 15 or 20% in volume," he said.

The export market provides American manufacturers with a place to sell their surplus. It is a market which they can always hold in reserve if the domestic market shows signs of weakening. If they have a foreign market for their goods they can often check a fall in prices by selling abroad rather than taking a loss at home. *This marginal market is a safety-valve which helps to prevent the accumulation of surplus stocks and a consequent depreciation in price.* Its importance was clearly shown by the fact that when it fell away in 1920, due to industrial depression abroad, industrial depression was precipitated in this country also.

Several readers of THE INDUSTRIAL DIGEST who favor the Fordney-McCumber tariff have written letters to the editor indicating that they do not see the importance of foreign trade, or the connection between imports and exports.

"I have very little sympathy with the general statement that we must let foreigners ship their merchandise into this country if we want to do any export business," writes N. F. Thompson, Jr., of the Burson Knitting Co., Rockford, Ill. "We will do export business when, and only when we can produce some article that they want at a lower price than they can produce it, or when the article is something that they cannot produce at

all. When these conditions are met they will buy our product regardless of whether our tariff rates are high or low. If it were necessary to let them ship an equal quantity of manufactured good into this country in order that we may ship a quantity of manufactured goods to some foreign country, what advantage would our foreign trade be to us?"

THE INDUSTRIAL DIGEST would answer this last question by asking a question in turn: What advantage is there in selling a man goods unless he can pay for them?

A man, or a nation, can pay for its purchases only by sending in exchange something equally valuable. International payments are made by means of bills of exchange, which are balances against each other. Each bill represents a shipment of goods. When the bills on both sides do not balance (in other words, when the United States is not receiving as many dollars' worth of goods from all foreign nations as it is shipping abroad) the balance must be struck in one of two ways. Either the foreign nations must pay by shipping gold to the United States, or we must extend them credit on our books.

The United States naturally feels hesitant about extending further credit to Europe. Moreover, we do not want any more of Europe's gold. We now have more gold than we know what to do with. Gold is useful to a country today only in sufficient quantities to supply its banks and its government with an adequate reserve. Beyond that point it is an impediment.

Therefore, the only way in which Europe can pay for what we ship her is by sending us goods—not necessarily manufactures, but any kind of commodity.

Mr. Thompson says: "We will do export business when, and only when, we can produce some article that they want at a lower price than they can produce it, or when the article is something that they cannot produce at all." Will it not be to the common advantage of the United States and of foreign countries if they can buy of us articles which we produce more cheaply than they, and we in turn can buy of them goods which they can produce more cheaply than we?

That is, in a nutshell, the case for international free trade. But before that theory can be put into practice to the advantage of the United States it must be subjected to important modifications. Industries that are essential to our national independence must be protected regardless of other considerations. Other industries need protection because of their youth or because they are accustomed to tariff aid, which should not be taken away from them suddenly. The protective tariff should not be entirely dispensed with, but used with moderation and in accordance with the needs of the day, which should be determined as accurately as possible by experts.

Does the Fordney-McCumber Bill meet the needs of the day? Or is it the result of political log-rolling, and will it consequently be injurious to industry?

The Trend of Dividend Payments by Industrial Corporations

Three factors influence the payment of dividends: (1) the earnings—dividends are not usually paid unless earned; (2) the financial position of the company—if ready money is needed, dividends are likely to be deferred; (3) the degree of confidence with which the directors view the future. The record shown above speaks more strongly of improved financial position and returning confidence than it does of increased earnings. A three-months' moving average has been taken in order to distribute the very heavy payments that come in January and July and to a lesser extent in April and October.—(United Business Service.)

Combinations in Pursuit of Trade

Many mergers being formed to eliminate uneconomic methods of distribution and thereby reduce costs

MERGERS, mergers, mergers. Ever since public attention was attracted to the attempts of certain independent steel companies to amalgamate, dozens of rumors about industrial consolidations have made the rounds. One day it is said that a great copper combine is being formed. The next day the rumor is about the railroads. Then the merger talk swings to oil, then to tobacco, then to sugar, and then back to tobacco, then to sugar, and then back again to steel, over which it continually hovers.

The chief stamping ground for these rumors is the Wall Street district. Speculators have to talk, or they couldn't speculate, and brokers must stimulate such conversation in order that commissions may accumulate. The steel merger rumors, of which a new variety appears almost every day, have been the basis of continual fluctuations in the stocks of independent steel corporations.

But the mergers talk should not be discredited because it is Wall Street gossip. Many of the rumors are wild, and there is often no reason for believing the current versions of expected consolidations—but where there is so much smoke there is surely some fire. At least two important mergers—that of the Bethlehem Steel Corporation with the Lackawanna Steel Co.—and the Midvale, the Republic and the Inland Steel Companies have been successfully negotiated. To be sure, they came as a surprise, and partly upset another rumored consolidation; but the fact that they were actually brought to a conclusion has strengthened the general belief that mergers in other lines also will be effected.

Will the Railroads Merge?

THE most important, yet the most vague, of the merger rumors that followed the Bethlehem-Lackawanna combination is concerned with railroads. A series of great transportation combinations is said to be on the horizon, but its form is not yet clear. Much study has been given by Government officials, railroad managers, economists and bankers to the subject of railway consolidation for greater efficiency, and an elaborate plan for the creation of 19 great American railway systems has been worked out and published by the Interstate Commerce Commission. But in business the recommendations of experts are not always followed, and the railway consolidations that are coming—if they are coming—may in no way resemble these plans.

A recent decision of Federal Circuit Judge Julius M. Mayer, permitting the New York, New Haven & Hartford Railroad to elect five directors to the board of the Boston & Maine, has been hailed as an indication of a change in Federal policy toward the union of railroads through interlocking directorates. It is expected that the decision will be followed by the application of many railroad and industrial companies for modifications of decrees which, under the Wilson administration, forced their separation from allied interests.

"The time has come," said Judge Mayer in his decision, "when, in respect to the operation and control of these railways, the mental attitude should be one of construction."

The Machinery of Production Is Far More Efficient Than the Machinery of Distribution.

In the tobacco trade a merger has been effected between the Tobacco Products Corporation and the United Retail Stores Corporation, which controls the United Cigar Stores Co. The consolidation will be accomplished by an increase in the capitalization of the Tobacco Products Corporation from \$33,000,000 par value to \$157,354,000 and the exchange of the stock of that company and of the United Retail Stores Corporation for the new tobacco products securities.

This is a combination of an important wholesaler with the largest retailer in its field, and the chief benefit will be the pooling of wholesaler's and retailer's profits. According to James M. Dixon, president of the Tobacco Products Corporation, the merger will enable the United Cigar Stores Co. to effect many changes in its operating methods. New blood will be injected, he said, and the expansion of the system will be continued.

The merger marks the return of James B. Duke to active participation in the tobacco business. Mr. Duke has been in comparative retirement since his resignation as president of the American Tobacco Co. in 1912, after the company had been dissolved by order of the United States Supreme Court. The new combine will be

under the guidance of Mr. Duke, with whom Mr. Dixon has been associated since his boyhood.

The oil trade was concerned for a long while with a rumor that the Sinclair Oil Co. would be taken over by the Standard Oil of Indiana. Just as Wall Street had virtually settled the terms of the merger President Sinclair said the whole story was "absolutely ridiculous." The Street thinks negotiations are being continued, and is talking about other oil mergers.

The steel mergers have been hitting snag after snag ever since the negotiations began. First Lackawanna deserted the group of seven independents to make a separate alliance with Bethlehem. Then the Youngstown Sheet and Tube Co. dropped out of the negotiations altogether.

After protracted negotiations, a consolidation of the Midvale Steel & Ordnance Co., the Republic Iron & Steel Co. and the Inland Steel Co. was announced. The combine will be owned by Midvale, the name of which will probably be changed to the North American Steel Co. The aggregate capitalization of the three companies is about \$251,000,000. Negotiations for the inclusion of other companies in the merger are being continued, it is said.

It has been rumored in financial circles that a sixth independent—several names were mentioned—would join the remaining five. A few days later it was announced that at the request of Attorney-General Daugherty all negotiations for a merger of independents had been called off until the Department of Justice and the Federal Trade Commissions could complete their investigations. The consummation of the Bethlehem-Lackawanna merger has been postponed for the same reason.

Efficiency of Machine Tool Plants

A comparison of the "value-added-per-man" shows the marked advantage of the large plant

SOME interesting economic facts in regard to the machine-tool industry may be gained from a study of the accompanying table, compiled during the last census and recently published in the Industrial Letter of the McGraw-Hill Company. The shops of the country making machine tools have been classified in four groups according to the dollar value of their product. The number of shops in each class is listed in the second column and the total value of their product in the third. The cost of the materials used is placed in the fourth column and the fifth column is obtained by subtracting four from three.

In class 2, over \$500,000 means over \$500,000 and below \$1,000,000. Summations are made below the first set of figures and show, among other things, that the total turnover of capi-

tal for the year is slightly less than one, 212,400,000 divided by 231,000,000, equaling 0.917, to be exact.

The fact that 80% of the product, measured in dollars, is made by 93 of the 403 shops, and that 95% is made by 277 is worth noting. Of those shops with an output of over \$1,000,000 13% turn out 69% of the total output. And when the number of wage-earners in each class of shop is taken into consideration it will be observed that the bigger the shop the larger the value of the product per wage-earner employed. The same thing applies to the added value per wage-earner. The struggle for existence confronting the small shop with inferior or inadequate equipment is still further indicated by the fact that even in 1919 it produced 25% less per wage-earner employed than the average of all the shops.

Keep Your Eye on the Coal Pile

Otherwise you may find it difficult to secure a supply when the country is fuel-starving

EVERY branch of industry is certain to be seriously handicapped if the coal strike continues through the summer. Although the effect of the suspension of work by more than 600,000 men is not fully realized by the general public, panic among the industrial consumers of coal is increasing. Stocks on hand are being rapidly depleted. Careful calculations show that while production in the non-union mines is now between 18,000,000 and 20,000,000 tons per month, the consumption is 35,000,000 and is still rising. By the middle of July it is believed the country will have no coal on hand and will be calling for at least 10,000,000 tons per month, more than all the non-union mines, working at utmost capacity, can furnish.

During the recent conference at Washington which was called for the purpose of fixing a fair price for coal during the strike, Secretary of Commerce Hoover asserted that withdrawal from stock amounted to between 3,000,000 and 3,500,000 tons a week.

"The time has arrived," Mr. Hoover said, "when the unwise virgins who did not heed my recommendations for stocking up with coal must go into the market to get it."

As time goes on more and more industrial consumers as well as the retailers of anthracite coal will be forced to go

into the market. The marked increase in iron and steel orders has rapidly depleted the huge stocks accumulated in anticipation of the strike. And in many other industrial plants stocks of coal have already been consumed. When the domestic users of coal realize the seriousness of the situation and begin buying, it is predicted that a shortage of anthracite will result and that, if the expected three months' shutdown takes place, overtime work at the mines after the strike will be necessary before the collieries can resume.

The Prospects

REPORTS from all Government departments indicate that a building and business boom is in prospect and that within thirty to sixty days unemployment will be reduced to normal, if the threatened coal famine can be averted. Operators of non-union mines and other operating mines, who have been in consultation with Secretary Hoover, assert that they can probably deliver 6,000,000 tons or more of coal each week and so avert a crisis. This amount, even in addition to the coal in storage, will not meet the estimated requirements if general business activities continue to advance on the present scale.

Strike leaders have announced that the miners are prepared to stay out all summer, if necessary, in order to win the strike, and that the union has made tremendous inroads in the non-union fields, many thousands of unorganized men having gone out with the union men and joined the United Mine Workers of America. It is also predicted that a new strike order, calling from the mines the 8000 maintenance men who have remained on duty since the suspension on April 1, may be issued, if the operators and miners do not reach an agreement in the very near future.

Commenting on the effect of the strike upon the coal market, *Coal Age* says:

"With the Lackawanna Railroad taking smokeless coal from southern West Virginia by barge from Hampton Roads, unloading the barges in New York Harbor into open-top cars for railroad fuel west to Buffalo, and with the reverse of this, the Pennsylvania Railroad taking smokeless coal off the Norfolk and Western, west and north to Columbus and then east to Manhattan transfer, one has

(Kansas City Star)

No Wonder the Old Boy Has a Nervous Disposition

a picture of the topsy-turvy conditions of the market in the East. The liveliest market centers in New York City and extends south to Baltimore. Except for waterborne coal from Hampton Roads, there is little tonnage available in these markets, and the inland buyer, who is not readily served by tide-water delivery, is becoming panicky. There are not many coal consumers in the market in this area, but the prices they have to pay for coal are increasing every day.

"For the coal from the one real source of supply, southern West Virginia, West Virginia and eastern Kentucky, the Atlantic seaboard is bidding against the steel industry and the West. Spread over the whole market is the beginning of heavy buying by the railroads. Chicago is leaning heavily on western Kentucky, a union field operating under a contract that runs throughout this year. . . . Demand for fuel for some steel plants on Lake Erie is moving coal in such volume from Toledo to Buffalo that boat rates have been marked up. It is reported that steel manufacturers at Sandusky have bought coal at Duluth and will ship it down. Canadian railroads are buying coal off the Duluth docks to be delivered by boat."

Millions Going Up in Smoke

DO you remember the story of the man who made a fortune in Pittsburgh laundering window curtains? The more smoke in the Pittsburgh atmosphere, the more curtains to be laundered. But his successors in the business will not make so much money if the coal-burning industries follow the suggestion of the Government and college experts working on the problem at the University of Illinois.

These authorities assert that by employing a specially devised low-temperature process it is possible to convert many supposedly non-cokable coals into coke. If this could be accomplished it would not only solve the smoke nuisance but at the same time result in the recovery of valuable by-products of ammonia gas and tar which have been going to waste. In the opinion of H. O. Loebell, of New York, chairman of the industrial fuel committee of the American Gas Association, there is a likelihood of gas entering all competitive fuel markets with its possible complete utilization for heating purposes by all industries of the nation. "If either (of these productions) is right," says *Commercial Fertilizer*, "then the day approaches when sulphate of ammonia will be a by-product of about all the coal that is mined in this country. This will mean considerable sulphate of ammonia."

The experiments conducted by the University of Illinois were undertaken in connection with an investigation by the Bureau of Mines of the smoke problem at Salt Lake City. It was found that coke was regularly obtained from only a few coals tributary to the Salt Lake City district, and that if the use of coke, a smokeless fuel, was to be increased in that city it would be necessary to demonstrate the possibilities of coking coal not regularly used for that purpose. Six coals

from various Utah districts were tested, although so far as present standards of coking indications are concerned, the coals tested seem quite non-coking. However, treatment by the methods devised by Professor S. W. Park, of the University of Illinois, is said to have resulted in a yield of good coke amounting to approximately 60% of the coal used. This coke is dense and of good texture and seems adapted to use as a domestic fuel and for metallurgical purposes. Slightly more than 20 lbs. of ammonium sulphate valuable as fertilizer were recovered per ton of coal coked.

The gas recovered as a by-product is especially suitable for utilization in city mains. And it is believed that the tar oils obtained will lend themselves readily to cracking processes, thus furnishing a product suitable for motor fuel purposes. These tar oils, on account of their exceptional drying properties, may also be available for paint and varnish manufacture. Other uses are suggested, such as direct combustion in engines of the Diesel type, as fuel for steam generation, as a source of heat for metallurgical purposes, the carbureting of water gas and as the source of pitch as a binder for the briquetting of lignite fuels, etc.

The report of the American Gas Association predicted that the gas industry will become the country's largest public service institution, and further asserted that gas companies must prepare themselves for a gigantic building program such as will permit them to take on \$1,000,000,000 of new business resulting from the task of providing heat for American homes and for industry. Complete disuse of solid fuel in cities and consequent elimination of smoke and grime were declared by the committee to be probable accomplishments in the near future.

U. S. Exports and Imports, 1914-1922.—(The Magazine of
Wall Street.)

Cotton Condition 69.6% Normal

ACCORDING to first report of condition of the cotton crop in the United States for this year, given out last week by the Department of Agriculture, the condition on May 25 was 69.6 per cent of normal compared with 66.0 last year, 62.4 in 1920, 75.16 in 1919, and 82.3 in 1918.

The condition of the cotton crop in the United States monthly and the estimated yield per acre are given below:

Years:	May 25	June 25	July 25	Aug. 25	Sept. 25
1922	69.6
1921	66.0	69.2	64.7	49.3	42.2
1920	62.4	70.7	74.1	67.5	59.1
1919	75.6	70.0	67.1	61.4	54.4
1918	82.3	85.8	73.6	55.7	54.4
1917	69.5	70.3	70.3	67.8	60.4

Condition of the crop on May 25 by States, with comparisons, follows:

	1922	1921	1920	Ten-year average
Virginia	91	77	71	83
North Carolina	84	65	70	77
South Carolina	67	58	68	72
Georgia	71	63	55	72
Alabama	80	57	58	72
Mississippi	75	60	65	76
Louisiana	70	57	72	75
Texas	61	71	60	76
Arkansas	76	70	61	76
Tennessee	79	69	60	76
Oklahoma	67	74	70	77
United States	69.6	66.0	62.4	74.6

Cotton acreage and yield per acre 1921 by principal States (revised estimates):

	Acres picked, 1921	Yield lint per acre, pounds
North Carolina	1,403,000	264
South Carolina	2,571,000	140
Georgia	4,172,000	90
Florida	65,000	80
Alabama	2,235,000	124
Mississippi	2,628,000	148
Louisiana	1,168,000	114
Texas	10,745,000	98
Arkansas	2,382,000	160
Tennessee	634,000	228
Oklahoma	2,206,000	104
United States	30,509,000	124.5

Hamburg's Tonnage Exceeds Figures of 1913

According to statistics just issued the tonnage of the shipping entering and leaving the port of Hamburg last month exceeded that of May, 1913, the year before the war.

Last month 1,143 vessels of 243,815,000 net tons arrived, as compared with 1,242 vessels of 193,526,000 tons in May, 1913. Sailings totalled 1,469, of 375,000,000 tons, as compared with 1,362 vessels, of 253,987,000 tons.

New Issues Slacken

THE bond market during the closing fortnight of May "continued to suffer from indigestion," as the financial editor of *The New York Tribune* put it. Brokers still had securities on their shelves left over from old offerings, and new financing was slackened to permit the market to complete the process of absorption. In the week ending May 27 the total offerings fell short of the \$100,000,000 average which had been maintained since the first of the year. Negotiations for numerous new issues were being conducted, but were slow to mature. Bond prices on the stock exchange held firm, in spite of a tendency of money rates to harden.

Public Utility Bonds

PUBLIC utility bonds had their turn as the leaders of the new offerings. Six new blocks of securities of this type, at prices to yield from 5.15 to 6.75%, were brought out by investment bankers during the week ending May 27.

Technical Position Stronger

THE stock market showed a tendency to react easily to favorable news. Apparently its technical position was corrected by the declines in the first part of May, and the way has been cleared for the continuation of the bull market. The averages for the month are as follows:

	20 INDUS.	Chge.	20 R.R.'S	Chge.
May 1.....	93.35	+.61	84.45	+.02
May 2.....	93.64	+.29	84.34	+.11

It will be observed that the brief downward reaction ended quite definitely in the middle of the month, and the daily change thereafter, with few exceptions, was upward. During the month the industrials rose from 93.35 to 95.61 and the rails from 84.45 to 85.54. The rails soon recovered the fractional losses they registered upon the announcement of the 10% rate reduction.

Rail Stocks in Demand

THE strength of the railway stocks, in spite of the rate order, is due to a combination of factors, according to the *Boston News Bureau*:

"If the reduction in rates is translated into retail prices, it will enable the public to increase its purchases, which will make more

work for manufacturers, increase movement of raw material to manufacturing plant and the shipment of finished product therefrom. Increased efficiency on the part of the men is also playing its part in reducing costs.

"One of the significant developments of the past few days is the report from Washington that President Harding is considering asking Congress to amend the Transportation Act, one of the changes being to remove seat of the Railroad Labor Board from Chicago to Washington. Evidently the Administration believes there should be closer co-operation and co-ordination of efforts between the Commerce Commission, as the rate-making body, and the Railroad Labor Board, as the wage-fixing tribunal. Action of the Commerce Commission in ordering a reduction in rates before the Labor Board announces its decision in the wage cases seems like putting the cart before the horse; but there is every reason to expect that the Labor Board will order some reduction in wage rates which will offset the cut in revenues that will follow freight rate reductions.

"The money market is another factor which is having a salutary effect upon the railroad market; and there are some investors who believe that with continuing easy money the time is not far distant when seasoned dividend-paying railroad stocks will be selling on a basis to yield little more than 5%. As many standard rails are selling today at prices to yield better than 6%, a decrease in yield to a 5% level would mean an increase in price of 20 points or more.

"Expectation of consolidations is also a contributory factor in the present rail market. No date has been set for hearings by the Commerce Commission on the subject; but consolidations will be made on paper from time to time, with bullish effect, particularly on the lower-priced issues. Railroad men point out that the consolidations as provided under the Transportation Act are not mandatory, and managers of the stronger system question whether the situation will be strengthened by addition of "weak sisters" to strong ones. Big systems, like the Pennsylvania and the New York Central, have been proceeding for some time in consolidating their systems internally and thereby reducing the number of different corporations embraced in the system, and so lessening expenses by consolidation of departments and elimination of reports."

The April report of 137 of the 201 Class 1 railroads shows net operating incomes amounting to \$35,239,000, compared with \$21,886,000 for the same roads in April, 1921. The railroads scored this substantial increase in net income in spite of the fact that their total operating revenues were only \$297,300,000, a decrease of 4.6% from the record of the previous year. Total operating expenses were \$240,533,000.

The reports of car loadings are also a source of some encouragement to railway investors. Loadings of revenue freight for the week ending May 20 totaled 792,459 cars, an increase of 15,100 cars compared with the preceding week and 21,468 more than the corresponding week of 1921. The May 20 figure was 69,615 less than that of 1920.

Good News for Reading Stockholders

BY a decision of the Supreme Court, rendered by Chief Justice Taft, the holders of preferred stock in Reading railroad and coal properties will benefit through the equal

distribution with the common stock of the surplus of past years in excess of dividends. The Chief Justice said that the rights of the common and preferred stockholders are to be determined by the organization agreement of 1896. Each share of stock, whether common or preferred, had

U. S. Government Bond Averages.—(Magazine of Wall Street.)

A view of what people buy and why. Perhaps the "no particular reason" is the nourishment of bucket shops.—From figures by Albert Frank & Co.

a vote. The agreement provided that the preferred stock should be entitled to non-cumulative dividends. The decision directs the District Court to ascertain values of the Reading properties and to divide lien and interest charges of the general mortgage between new companies in proportion to such values.

Financing Mexico

ADOLFO DE LA HUERTA, Secretary of the Treasury of Mexico, arrived in New York on Memorial Day for a series of conferences with American bankers. He expressed confidence that an amicable arrangement would be made. The conferences were to deal with the Mexican Government's financial obligations, the government railways and the oil industry.

The external bonds of Mexico, on which it is hoped to start payment soon, as a result of agreements to be reached by the conference, have been in default since 1914. The bankers expect Mexico to devote to this payment a fund of \$6,000,000, which was paid to the Mexican government in tax adjustments by American oil corporations. The bankers have let it be known that they do not expect the whole obligation to be discharged at once. Their objective at the conference, it is said, will be the payment of a moderate first instalment to be distributed among holders of the defaulted coupons, and reasonable guaranties that the balance will be paid and future interest payments made when due.

Mexico is credibly reported to be seeking a substantial loan in this country to help her to regain her feet. It is fairly safe to say that she will not get it unless she can satisfy the bankers' requirements as to her outstanding obligations.

Farm Bloc Wins Out

THE House of Representatives has passed the bill, approved several months ago by the Senate, providing for the appointment of an additional member of the Federal Reserve Board to represent agricultural interests. The farm politicians succeeded in taking this step in spite of the opposition of the Secretary of the Treasury, the Governor of the Federal Reserve Board and all others who resent the further intrusion of politics upon business.

Before passing the bill the House rejected amendments proposed by the House Banking and Currency Committee.

which struck out the provision for enlarging the Board and merely directed the President to have due regard in making appointments for the representation of agriculture. The bill as passed provides that in selecting the six appointive members of the Board "the President shall have due regard to a fair representation of the financial, agricultural, industrial and commercial interests and geographical divisions of the country. Not more than one may be appointed from any Federal Reserve District."

Passage of the bill in this form may enable W. P. G. Harding, governor of the Board, to continue in office after his present term expires in August. It had been expected, if the Board were not to be enlarged, that President Harding would name a Republican acceptable to the farmers in place of Governor Harding. Since a new place has been provided for the "dirt farmer," this step will be unnecessary. It is noteworthy that in spite of this fact Governor Harding opposed the bill as passed.

More Foreign Investments

MORE and more people appear to be reaching the conclusion that the investment abroad of America's surplus capital offers at once an attractive opportunity and a solution of the problem of our economic relations with Europe. We must export capital before Europe can pay her debts to us and conduct an extensive trade with the United States.

"The possibilities of foreign investment fall into two general classes," says *Barron's Weekly*. "We may either lend our money abroad or we may participate directly in the risks and profits of foreign industrial, mining and public service enterprises. These two broad fields may again be sub-divided. We may confine our loans to foreign governments or we may make loans to foreign business organizations. We may participate in foreign business either through the extension of the activities of American corporations to foreign fields, through the organization of investment trusts after the British model or through the direct purchase of stock in foreign corporations. Finally we may combine the functions of lenders and entrepreneurs by purchasing bonds of new enterprises with common stock bonuses."

"It is possible for Americans to co-operate for foreign investment on a generous scale with minimum risk through the medium of investment trusts, carefully organized and competently managed. Here is a virgin field for American initiative."

IN THE MANAGER'S OFFICE

Developing a Planning Department

CHARLES T. SIMPSON, in *100% Management*, outlines the development of a planning department which increased production at lower unit costs, reduced the overhead and relieved foremen of clerical and follow-up work. The planning department originates all manufacturing orders and material requisitions and assigns jobs in accordance with its schedule. Orders are sent from the sales department direct to the planning office, where material requisitions are made out and a progress record started for each job. This record shows the customer's name, information concerning the order such as size, quantity, date ordered, promised and completion dates and the details of the material requisition. Job tickets for each operation are prepared at the same time and are placed with the progress record in a pocket on the job control board.

On this board a system of colored pegs shows graphically work ahead, work assigned or in process and work finished. This is shown with reference to operations only. A separate board shows the jobs in process and as assigned to each operator. Each department in the factory is provided with an assignment board which has three pockets opposite every operator's name. When a job is sent from the planning office to the factory a messenger takes the job tickets from the job control board and distributes them to the department boards. When an operator finishes a job he punches his ticket on the clock and drops it in the "finished" box, taking the next assignment from one of the pockets on the assignment board. Two messengers make trips every half hour to collect the finished job tickets and correct the control boards.

When an order is first received from the sales department, a request for materials is sent to the stockroom, where the materials are assembled for delivery to the proper departments for the delivery of materials at the proper place and time, so that operators are not kept waiting for stock.

Committee Control of Costs and Profits

CONTROLLING costs and establishing profit margins by committees representing the entire organization is advocated by *Industrial Management*. The primary functions of the committees are: The analysis of manufacturing costs and expenses; detailed waste surveys in assigned processes; budget control and revision; suggestions for specific cost cutting.

The work is done by a central or coordinating committee controlling the activities of five general committees on men, methods, machinery, materials and money. These committees are further subdivided to study problems in their respective fields. The coordinating and general committees are made up of officers, major and minor executives and key men. Individual members of the entire personnel are drawn upon as temporary members of the various sub-committees and are urged to bring forward suggestions and constructive criticism regarding the work of any sub-committee.

The money committee first makes a study of expenditures to segregate those items of expense which are considered promising fields for effort toward economy. The high spots are thus determined. The Committee then reports its findings and recommendations to the coordinating committee, which in the meantime has listed the weak spots. The correlation of high spots and weak spots determines the work of the other committees.

The next step is to sell the plan to the organization as a whole, and this is the function of the committee on men. The plan is explained so that every member of the organization

realizes that it will work to his personal advantage in permanency, full-time employment, good wages and better working conditions.

The remaining general committees—methods, machinery and materials—make surveys, receive suggestions and make recommendations on technical features of the manufacturing process. Each member of the technical sub-committees discusses the problems of his committee with as many members of the organization as possible. Current technical publications are used for ideas as to how other concerns handle the same problem. Every step in the manufacture is questioned as to its necessity and after its necessity is established the efficiency is determined.

Computing Bonus Payments

A METHOD of computing bonus earnings and direct labor costs under the group bonus plan is described by E. K. Wennerlund in *100% Management*. Each group is designated by a number or symbol which is used by the cost department as the operation number. The personnel of a group may change without affecting the group symbol. A shop routing sheet is prepared for each part or assembly on which work is done by the factory and shows all the detail operations with their standard times. The detail operations are combined into group operations. A copy of the shop routing sheet is furnished the cost department. Group operations then become the basis for computing direct labor costs.

The shop check turns in daily the list of clock numbers of employees assigned to each group, showing the actual number of hours each employee worked in the group. These hours are taken from the entrance clock cards. If an employee is transferred from one group to another during the day, a transfer slip is made out by the foreman and time charged accordingly. The total clock hours each day per department must balance with group hours plus any individual job tickets. These hours are entered daily by the bonus clerk under clock numbers. Credits are summarized from inspection slips and given to the bonus clerk.

At the close of the pay period the total hours for each employee are added and multiplied by the base rate to give the amount on which the bonus is computed. The ratio of standard hours to actual hours measures the group efficiency. Direct labor cost of the group operation is obtained by dividing the total cost of the group by the total number of pieces credited. The total cost of the group divided by total standard hours gives the cost per standard hour.

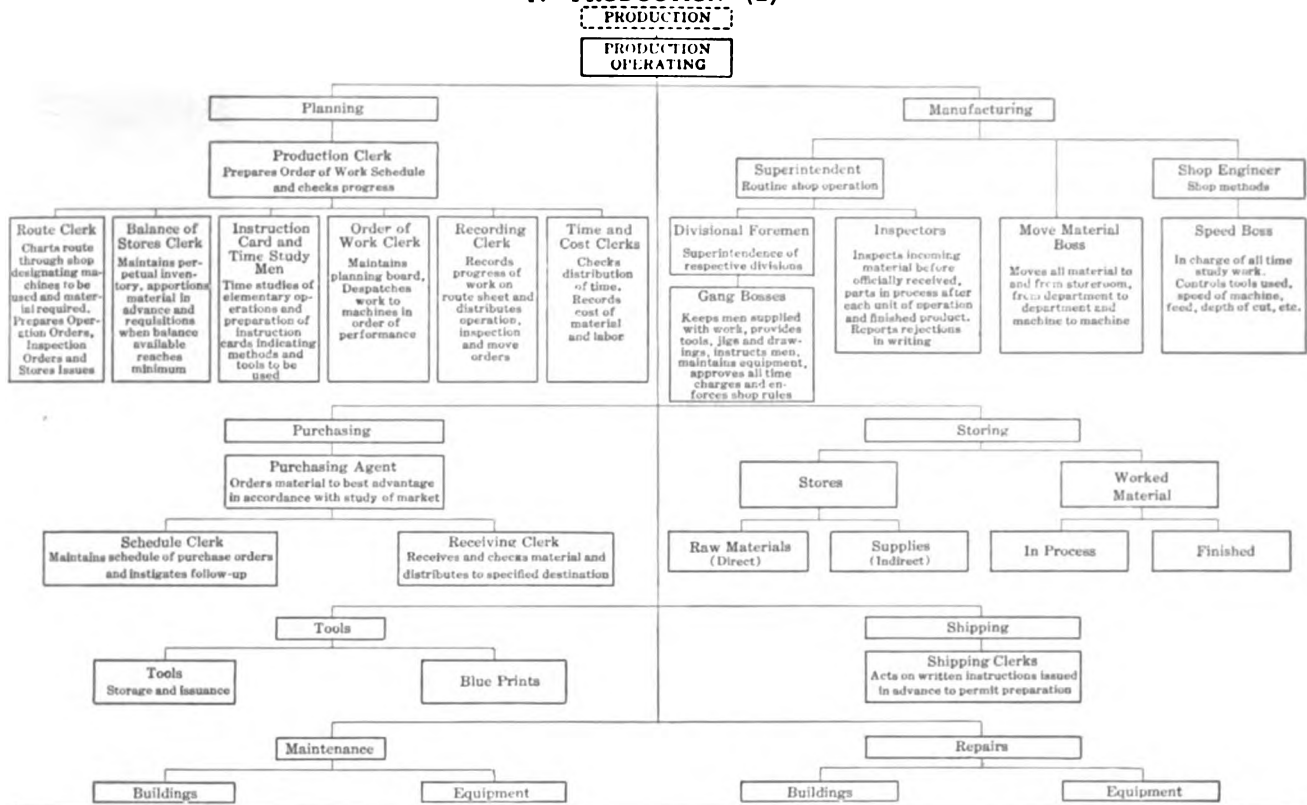

Job tickets or elapsed time checks on different parts are not required, nor is it necessary to check up quantities if an employee leaves early or is absent. Bonus is computed from the average efficiency attained by the group during the pay period.

An Executive Formula

MEASURING the apparently intangible quality of executive ability by mathematical formulae is proposed by Wm. E. Dunn in *Industrial Management*. The basis of the method is the contention that action may be measured in terms of its effects or results. Three factors in the measurement of executive ability are given. (1) The ratio of the amount of results accomplished to the time required in performance is the rate of production. (2) The value of the results divided by the costs of production gives the rate of increase in value. (3) The ratio of the product of the difficulties encountered to the sum of the means available for use is the "measure of the situation." The product of (1), (2) and (3) is the index of executive ability.

FUNCTIONAL ORGANIZATION OF A MANUFACTURING PLANT

IV PRODUCTION (2)

Functions of a Typical Industrial Plant

This chart is fourth in a series based on lectures given at the Bureau of Personnel Administration by Warren D. Bruner.

Some explanation is necessary as to how these expressions are obtained. Value of results, costs and means available (resources, assets and capital) are measured in terms of money. In the measurement of difficulties Mr. Dunn proposes a scale of difficulties based on job analyses, the difficulty of a job being inversely as the percentage of candidates who are able to attain the standard performance. If 50% of the candidates are successful the difficulty is 2, and so on.

Why Do Salesmen Fail?

WRITING from the buyer's viewpoint, E. E. Shumaker, in *The Purchasing Agent*, analyzes the factors which may be responsible for lack of success in selling. (1) A purchasing agent cannot buy from every salesman that calls. (2) The reputation of the company is often the deciding factor regardless of the qualities of the salesman. (3) Many organizations have established sources of supply for every important article and rarely change without good reason. (4) Sales campaigns are often directed at firms which do not have use for the article. A carefully planned prospect list will eliminate this feature. (5) In establishing new sources of supply the salesman himself is a very important factor and should be a good advertisement of the firm he represents. (6) A firm is not entirely judged by its representative, but a bad impression is created if the salesman is not a good advertisement.

Cheaper Handling of Stores

STORES are money and to prevent waste the handling of stores should be centralized and carefully controlled. The functions of a good stores system are: (1) To know what stock is needed for the prompt and efficient management of a business; (2) To know where each and every item of stock is, so it can be promptly obtained with a minimum of cost for getting it out of stores and into use, and to keep absolute

control of it while in process of manufacture; (3) To have stock on hand when it is needed, and to provide a means to automatically replenish stock getting low before it is entirely exhausted; (4) To know the amount required for the prompt and economical running of jobs and the fulfillment of the orders; (5) To prevent tying up of material, labor and its share of overhead expense in too large quantities; (6) To know that a correct balance is kept, so that stores on hand at the end of one month, plus that purchased that month for stock, minus that drawn out the same month, exactly equals the balance found to be on hand at the end of that month; (7) To know that all material used (with a minimum of waste) has been properly charged to an expense or job, and the stores account credited; (8) To give an exact record of the consumption of each item for any period, where each lot was obtained, when, in what quantities, the whole cost, or correct inventory valuation of it, and for what each piece was used; (9) To keep a perpetual stores ledger up to date, showing the unit balance (either piece, pound, foot, or other unit of measure) and a correct inventory value for the quantity on hand at that date; (10) To insure and maintain the accuracy of the stores ledger perpetual inventory, including the automatic checking of the same, both by classes as well as for each item each time stock is ordered to replenish a depleted supply.

New Paint Primer for Wood

FROM German sources comes the report that a solution of casein in sal ammoniac will give a primer that can be used to good advantage in painting all sorts of wooden surfaces, even the most porous. The primer will fill up the pores of the wood completely in one coat and the paint can be applied right over it after it has dried to give a smooth, even film. The ease of preparation and the cheapness of the primer recommend it for wide application.

The Railroad Wage Cut

THE announcement by the Railway Labor Board of the wage cut for maintenance-of-way men was the outstanding feature of the last fortnight. The opinion of labor publications seems to be that the cut, which is to be the first of a series affecting all railway employees, was intended to pass on the recent rate cut of the Interstate Commerce Commission to the workers. Consensus of newspaper opinion seems to be that the wage cut was in large part deserved and comes at a particularly fortunate time.

The officials of the maintenance-of-way employees' and railway shop laborers' unions have begun plans for a strike vote among the 478,000 members of the unions and approximately 75,000 non-union men who would be affected by any walk-out in protest of the wage cut. The cut will have the effect of reducing the wages of maintenance men from one to five cents an hour, depending upon the degree of skill required in the work.

Labor publications point out that the Interstate Commerce Commission had explicitly stated that no wage cuts were taken into consideration when the 10% horizontal rate reduction was decided upon and that further rate reduction might follow any announcement of a wage decrease.

It is generally understood that decisions affecting the wage scale of shopmen, clerks, station men and train service men will follow at an early date.

The effect of the wage cut has been chiefly to reassure railroad executives and holders of rail securities and at the same time to stir up animosity on the part of the unions affected. Railroad officials emphasize the fact that public opinion at this time would be very strongly against any protest of the wage reduction and express the opinion that no trouble will be forthcoming from the union.

Labor publications are strenuously opposed to the policy of the Railway Labor Board in handing down decisions affecting only one group at a time—a method which consists in practice of "singling out one man in a crowd and knocking him down." The claim is made that sufficient time elapses between one wage reduction and the next to permit any organized opposition to the decision to burn itself out without harm.

A meeting of the sixteen railroad brotherhoods and executives of other railroad organizations will be held in Cincinnati to consider the wage reductions which are contemplated by the Labor Board.

Textile Strike Shows Improvement

THE textile strike in New England shows considerable improvement. A Federal conciliator is operating in New Hampshire and is meeting with considerable success. Strikers in Somersworth, N. H., have notified the State Labor Commission that they would accept its recommendations laid down at a joint conference of mill owners and workers. These recommendations were that the strike be declared off; that employees be reinstated without prejudice or discrimination; that the working time for women and for minors under 18 years be 48 hours per week; that all wage reductions be submitted to a board of arbitration; that the decision of the board be accepted without further discussion; and that the decision should be retroactive to the time employees returned to work.

A legislative committee will probably be appointed in Massachusetts to deal with the Lawrence situation. No improvement is recorded in Rhode Island and the strike is increasing in bitterness, with injunctions and counter-injunctions crowding the horizon.

If a definite settlement should be reached in the New Hampshire mills it will immediately be made the basis for a working

How the Hearst Papers View the Labor Situation?

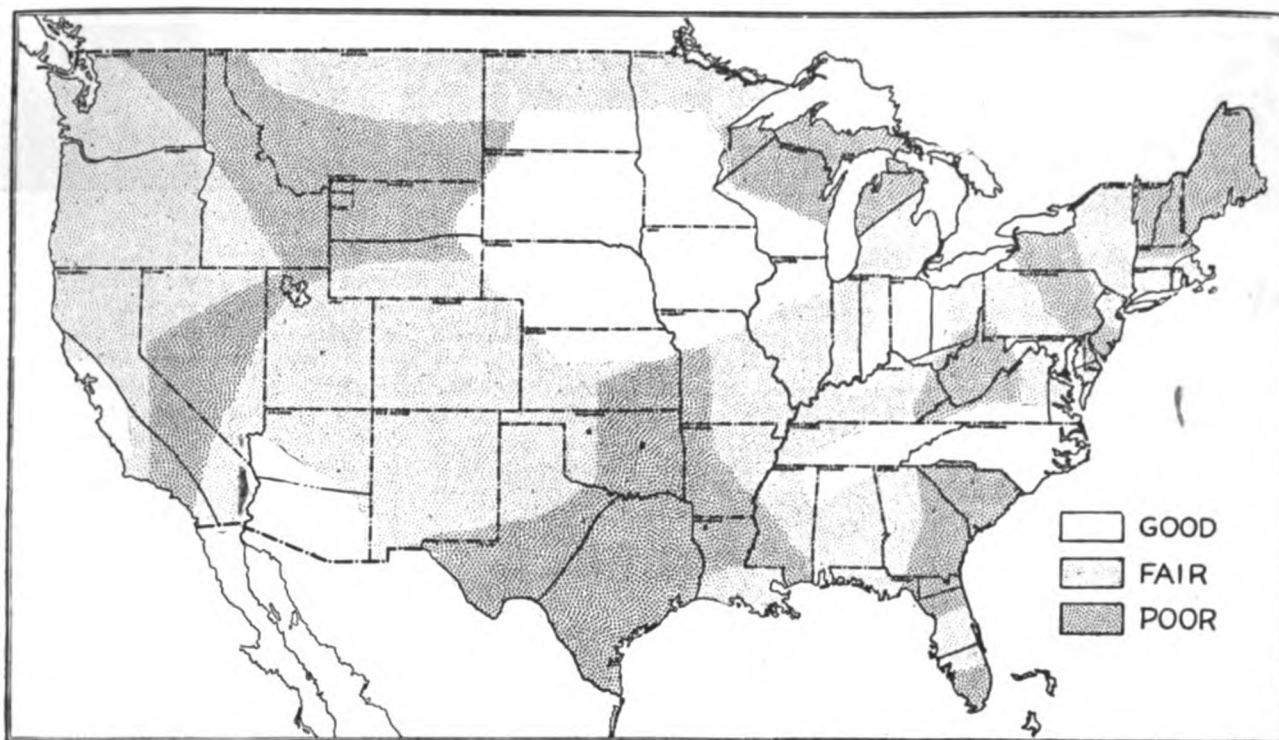

(New York American)

It's Surely Coming

(New York American)

One More Move and It Is Finished

Engineering Employment Conditions in Various Parts of the United States

Based on a survey in 200 widely separated localities. The most important factor in engineering employment is the apparent attainment of a much greater degree of economic adjustment and stability. The situation is far more promising than any that has prevailed for some time. The demand for architectural designers, structural draftsmen and designers, with building experience, far exceeds the supply in the Central West. Salaries for men of this class of work have increased very materially. There are a few positions opening up for construction engineers and superintendents.

agreement in the Rhode Island and Massachusetts mills, and the strike will be practically over.

Skilled Labor in Demand

THE National Industrial Conference Board reports that the shortage of skilled labor is increasing. In Boston, New York and New Jersey the shortage is confined for the most part to building trades. In Chicago, Detroit and other Middle-Western cities it is not limited to any one industry, but is said to apply generally. At various coast ports seamen are especially in demand, and the opening of the navigation season on the Great Lakes has influenced the movement of longshoremen from coast ports to the Lakes. According to the Weekly Survey issued by the National Industrial Conference Board, "Thousands of idle men are being taken on at iron mines in Michigan; these mines have been closed for a year, but some are now operating with full crews day and night. The agricultural industry, the building trades and the iron, and steel, automotive and railway car construction industries are steadily increasing in activity and are influencing conditions in industries connected with them.

"Better employment conditions are being reflected in materially diminished wage reductions and in increasing reports of wage advances. A summary of wage changes during the last month, prepared by the National Industrial Conference Board, shows that in the clothing industry wage reductions are on the increase, that in the building trades the number of cases of reductions is one-third lower than during the previous month, that in the granite industry a 20% reduction has been accepted and a strike ended, and that in a few cases attempts to reduce wages have failed."

Cost of Living Stabilized

THE cost of living in the United States, as a whole, has not changed, according to the National Industrial Conference Board's recent investigations, which show that "on April 15,

1922, the cost of living was 54.8% above what it was in July, 1914. This represents an increase of less than one-tenth of 1% since March 15, 1922. The only change in the entire budget within the month was a slight increase in clothing prices which had an insignificant effect on the budget as a whole. Dealers are of the opinion that there will be little or no change in clothing prices within the next few months and real estate operators report the same regarding house rents. The future price of coal for domestic use is said to depend largely on the outcome of the present strike in both the anthracite and bituminous fields."

Employment Increases by Trades

ACCORDING to a report of the United States Bureau of Labor Statistics, four industries show an increase in the number of persons employed, and eight a decrease in April, 1922, compared with March, 1922. Industries which show an increase in employment are: iron and steel, 6.8%; automobile manufacture, 6.3%; car building and repairing, 0.2%; and hosiery and underwear, 0.1%. Decreases were shown for cotton finishing, 15.1%; men's clothing, 10.1%; silk manufacturing, 9.5%; boots and shoes, 5.7%; paper making, 5.6%; cigar manufacturing, 5.3%; leather manufacturing, 2.7%; and cotton manufacturing, 2.0%.

Benefits of the Five-Day Week

ALTHOUGH the five-day week, recently put into operation by Henry Ford, is not new, having been previously adopted by the Clothcraft Shops in Cleveland, Ford's plan is found to have a number of advantages resulting from its use. Chief among these are the saving of power—the same output in 10% less time; reduction in absence and labor turnover; new sources of labor—women coming in for five days who could not for six; more balanced production.

Of 40 firms, in shoes, textiles, rubber and metals, that have tried the five-day week, the majority have reported favorably.

ADVERTISING

Use Color to Make Your Letters Pull

WHEN a salesman makes his call, his success depends entirely upon his ability to find the vulnerable point of his buyer—the point to which the appeal can be made with the greatest chance of success. And James H. Rothschild, writing in *Forbes Magazine*, points out that modern letter-writers are working along the same lines as the salesman. As the result of carefully conducted tests it has been found that letters on certain colors of stock make for quicker action than others.

In a recent test 12,000 letters were sent out—1000 each of twelve letters. The same copy was used in each case, the only difference being in its "dress" and the color of the stock used. The total was divided into four territorial groups—North, South, East and West. Six of the letters were illustrated with cuts and six were not. All were made up and signed on the multigraph, but each was filled in by typewriter to match.

As a result of the tests it was found that a letter on plain white stock, with a conventional letterhead, pulled 9%, while the same text on pink stock with two little line cuts pulled 48%. Table I shows you just which colors are most popular, while Table II shows you the duration of pull of the various letters. It should be noted that nearly 46% out of the 48% total replies received to letter No. 12 came in two weeks, whereas letter No. 1 took five weeks to reach 9%.

How Much Do Women Buy?

ACCORDING to Herbert N. Casson, women buy 76% of all the merchandise in the shops. They spend three times as much money as men do, for they buy for themselves, for the children, for the home, and to quite an extent for the men of the family.

The percentage of certain goods bought by women is silks 95%, books 85%, toilet goods 95%, jewelry 90%, glass and china 75%, leather goods 65%, pianos 75%, phonographs 60%.

But in spite of the

fact that women are the purchasers of such a large portion of merchandise, it is pointed out that in all the mass of instructions on how to write effective advertising copy, little consideration is given to the woman's viewpoint, and that among the many books on advertising there is not a single manual devoted to the best method of appealing to the woman buyer.

How Industry Can Avoid Summer Depression

IN the opinion of Edward Eyre Hunt, writing in *Printers' Ink*, seasonable employment, like the cyclical movement over seven-to-ten-year periods, is control-

lable within certain limits. It is believed that miscalculation of demand, more than anything else, intensifies the upward and downward movements of business. Intensive analysis of markets and extra sales efforts must be started today if summer is not to slow down the momentum business has already gained.

If every manufacturer would start in tomorrow to study his sales in terms of volume, and then use the money he is spending for sales effort to control the volume intelligently during the period just ahead, it would help materially to a better business, instead of the usual summer slump.

Testing Mail Order Advertising

ONE of the greatest advantages in using mail-order advertising, says Verneur Edmund Pratt in *The Mailbag*, is that it can be quickly tested. In a few days or a week after mailing one can begin to tell whether it is going to pay or not.

All mail-order plans may be tested in one of the following ways:

(1) By testing one city, county or State, and from the results obtained in this one spot computing probable results from big mailing.

(2) By testing a small mailing scattered over the entire territory and computing results from large mailing.

(3) By testing either one piece of merchandise or a small group of articles and from the results computing the returns from a full showing.

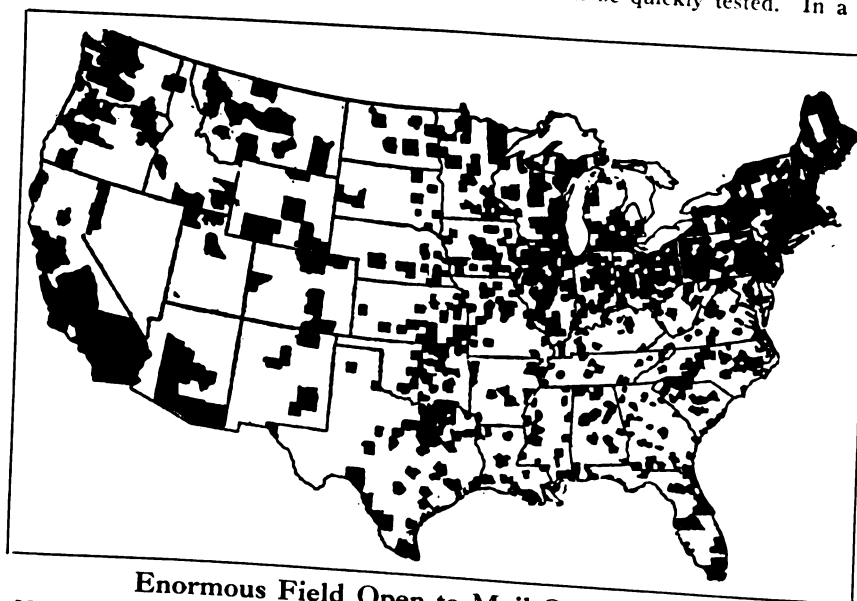

Table I
Results of Color Test

Letter No.	Quantity	Color	Cuts	Color Envs.	Pull P.C.
1	1000	White	No	White	9

Enormous Field Open to Mail-Order Houses

Mail-order houses do a large business in communities of as high as 25,000 population. In the map above, the black spaces represent those sections of States in which are counties containing towns of 5,000 or over. Assuming that mail-order concerns must look to strictly rural communities for the bulk of their business, the white area shows the enormous extent of the territory which they can serve, especially in the Mississippi River Valley.—(*N. Y. Evening Post.*)

EXPORT • IMPORT

Export Prospects Brighter

THE effect of the anticipated consummation of a German loan has been reflected in the remarkable improvement of European exchange and particularly in the strengthening of sterling and of marks, the former reaching \$4.46, the highest since mid-July of 1919, and the latter rising to 38/100ths of a cent. The fact that the German Government submitted to the terms laid down by the Reparations Commission, and that France accepted the submission of Germany as satisfactory, is likely to have a tremendous effect not only upon conditions abroad, but upon the export trade of the United States, since the rise in exchange will make American goods easier to sell in foreign markets.

Our Foreign Trade Situation

"THE European industrial situation is by far the most outstanding single factor in our foreign trade," according to Dr. Julius Klein, director of the Bureau of Foreign and Domestic Commerce. Speaking before the First National Convention of American Importers and Exporters, New York, he declared that "it is by all odds the most conspicuous beacon on our commercial horizon by which our overseas efforts are to be guided. On the one hand, it shows the way to those markets across the Atlantic which buy every year nearly 60% of all our exports. On the other, it indicates the possible menace of European competition with American goods in other markets such as the Far East and Latin America. The Continent as a whole," said Doctor Klein, "and especially the United Kingdom, which is by far our best customer, is getting back to normal production of food-stuffs and, unless a new drought or crop failure occurs this season, will import reduced quantities of edible necessities. Although some populations, notably those of the Eastern and Central countries, are economically exhausted along many lines, many new operations are going on for the improvement of their productive capacity. The German Government, for example, is spending large sums on the improvement of the permanent equipment of the German railway system, the French and Italian Governments are carrying out large schemes for the utilization of water power, and several canal and other important public projects are under way.

"The various European countries are gradually returning to a saner political outlook and to a more complete recognition of their own economic situation. France is gradually realizing that its budget must be balanced out of current revenues, and that it cannot rely on German reparations. Italy has been able to effect cuts in government expenditures and is weathering the crisis caused by the Ansaldo and Banca di Sconto troubles. Germany is coming to the end of

its artificial boom, and since German competition, maintained by depreciating currency, has been unfavorably affecting trade all over Europe, Germany's effort to balance its budget, under allied pressure, will have a widespread favorable effect."

Demand for U. S. Products Increasing

THE tendency toward a gradual increase and broadening in the foreign demand for American products has continued during May. Automobile exports have been increasing rapidly, and it is reported that manufacturers of several of the less expensive but well-known makes have received orders which are beyond their capacity to fill. England, at present, is the most active market, and other countries of Europe and South America are buying more generally than a few months ago. Copper has also continued to sell actively abroad, the Orient, Germany, and France being the chief purchasers. April cotton exports were 598,000 bales,

an increase of 137,000 bales, compared with the March total, and the largest total since December.

Export Advertising Records

ACCORDING to James S. Martin, speaking before the Foreign Trade Convention in Philadelphia, a system of home-office record-keeping is essential for the advertising exporter. The most important of these are (1) A card index of branch office and dealer imprints. It is best to obtain these imprints directly from

the field, and to keep them listed in two forms: (a) a complete form which will include all the sub-offices and selling agents under the main branch or dealer, this imprint to be used whenever space permits; and (b) a brief two- or three-line imprint for use on posters, calendars, and other items in which the imprint is subordinate and a small space is appropriated for that use. (2) A card index of branch offices and dealers with a complete running record of all advertising material and special allowances sent or granted to them, together with the date of order, quantity, method of shipment. (3) A card index of all current items of advertising material. (4) A card index of shipments, which should consist of two files: (a) cards showing advertising shipments on order, and (b) the same cards removed to the second file when the goods have been forwarded. (5) A card file of dealers' percentage allowances for advertising. (6) A file of imprinted samples. Each catalog, folder or other item which is especially imprinted for a dealer should, whenever possible, be recorded by a sample in this file. (7) A file of clipped advertisements from all the foreign territories to which you export goods. This file has been found extremely valuable if it is properly used as an exchange.

Index of Volume of Exports.

Index of Volume of Imports.

(1920 Quarterly Average = 100).—Harvard Economic Service.

AUTOMOTIVE

Automobile Export Prospects Excellent

A GENERAL survey of the foreign markets indicates that American automotive products are competing successfully with those of other nations. The favorable factors for the American exporter, says *Automotive Industries*, are the quality of the products themselves and their low price while the unfavorable factors are the rate of exchange with the various countries, and the high tariffs. However, foreign demand has increased to such an extent that it not only compares favorably with the better situation prevailing in the domestic markets, but reflects the improvement in business conditions throughout many parts of the world.

It is probable that the 1922 shipments of automobiles and of tires and accessories will exceed those reached in 1919 and that the year's trade will be the second largest in the history of the industry. This prediction seems warranted by the business already done, particularly in passenger cars, tires and equipment, and it is believed that later months of the year will not see any slackening of foreign demand.

An evidence of the progress made by the United States in foreign markets is indicated by the following figures recently published by the New Zealand Motor Trade Association:

Origin of Imports	1919	1920	1921
Cars	Percent	Percent	Percent
Canada	54	44	32
United States	44	46	42
Great Britain	2	10	20
Continent	6
Trucks and Lorries			
Canada	70	58	35
United States	27	26	30
Great Britain	3	16	29
Continent	6

Total values, incl'd'g chassis, £1,125,088 £2,921,173 £1,210,762

Facts about the Chain Drive. Chief engineer of one of the largest chain manufacturing companies gives some simple but apparently little-understood facts about chains and their use. He gives the advantages of chains for final drive on motor trucks, and develops each of these. Then he goes into the care of chains, with reference to proper adjustment, lubrication, cleaning, enclosures, etc. Winds up with a list of possible chain troubles, due to bad design, bad workmanship, bad installation, wear, neglect or abuse. G. M. BARTLETT, *Commercial Car J.*, 4-15-22, 3100 w. MAH.

Motor Truck Indispensable to Lumber Industry. Experience of a number of widely differing concerns, with very divergent problems, located all over the known world, shows that in almost any lumber situation the truck is a necessity,

as compared with horses or other means of transportation a great economy, and in the majority of cases an actual business getter. Experiences cited include getting out veneer logs in December in Wisconsin, hauling out huge timbers in a Southern camp where it acts as a locomotive working on wooden rails, hauling supplies to a Maine logging camp, getting in the firewood in the Far West, doing irrigation work on cut-over lands in the Central West, etc. *Motor Truck*, 3-22, 5100 w. MAH.

Laminated Automobile Suspension Springs. Author treats of their design and functioning, taking up in order such topics as vertical acceleration, nomenclature, determination of stress from strain in bending, weight and reliability, strength stiffness and resilience, etc. A. A. REMINGTON, *Automotive Industries*, 4-6-22, 6100 w. MAH.

Expediting Body Finish by Drying Equipment. Recent years have focused the car manufacturer's attention on the body, and they are now trying to make them as cheaply as possible, without reducing the quality. This has brought forth a demand for quicker painting and finishing methods, with the result that several lines of rapid drying equipment have been developed to speed up the drying of painted and varnished surfaces. So far has this gone, in fact, that one well-known light car is painted every 59 seconds, that being the time it takes a body to pass through the long drying oven, after it has been sprayed with paint or enamel. This article describes ovens used at Franklin and Chalmers plants, and presents a layout of a progressive system for rapid finishing. Also a schedule of operations for low- and medium-priced cars, and one for very high-grade work, using the drying equipment. J. E. SCHIPPER, *Automotive Industries*, 3-30-12, 3000 w. MAH.

S. A. E.'s Recent Standardization Work. Describes in detail recent parts, units or dimensions standardized by the Society of Automotive Engineers, or worked upon by its various standardization committees. There have been changes in the ball-bearing standards recently, new recommendations have been made on passenger car bumpers, new iron and steel specifications, leaf spring stock, rolling tolerances for concave spring steel, etc. *Automotive Industries*, 4-6-22, 2950 w. MAH.

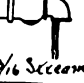

Significance of Rear Wheel Dynamometer Tests to the Engineer. A description of the car-testing apparatus installed at the Sheffield Scientific School at Yale, and the methods followed in its use. Significance of the data now being obtained to engineers generally, study of test results, rolling friction, wind resistance and tractive effort, efficiency of power transmission, fuel economy at various loads, etc. HERBERT CHASE, *Automotive Industries*, 4-20-22, 7500 w. MAH.

Monthly Exports and Unit Values of Passenger Cars 1913-1922.—(U. S. Commerce Reports.)

New Type of Compensating Differential. The differential used in all motor cars and trucks to give a different travel to each rear wheel when turning corners and in other situations, does not act correctly, since it differentiates for resistance, when it should differentiate for distance. That is why the average car becomes useless when one wheel is driven over glassy ice or is bogged down in deep mud or in similar situations. Many new forms have been designed with the idea of overcoming the drawbacks of the present form. The one which this article describes, the Krohn, utilizes the effects produced by fluid friction, and gives the greatest differential action at the lowest speeds, which is a very desirable point. The resistance increases as the speed increases. The essential parts of the device are double eccentric rollers, journaled in central driving plates fastened, respectively, to the two axle shafts. The driving plates also constitute an external and internal gear, respectively, which mesh with mating gears attached to the two axles. The driving plate external-internal gear unit can swing around the axis of the double eccentric when actuated to do so by the gears on the axle drive sections. When motion in the differential is induced as in turning corners, the internal gear on one axle and the external gear on the other turn in opposite directions. The compensating action consists of a swinging, gyratory motion around the centers of the supporting eccentric rollers. This motion causes them to rotate on their axes at a much greater rate than the shaft gears, the ratio in the Ford replacement unit being 12 to 1. The article describes the device more fully, and gives sectional drawings and photographs which help to make the action more clear. *Automotive Industries*, 4-20-22, 950 w. MAH.

The Chart Above Shows the Amount of Oil Lost, Due to Small Leaks.—(Canadian Ford Owner.)

is simple, quick, and is claimed to be very useful. It requires no other tools than the usual draftsman has, and a planimeter for measuring the area. ROY G. MILLER and F. E. SEILER, JR., *Aviation*, 3-27-22, 1600 w. MAH.

Commercial Aviation Developments in Europe. After general introduction citing advances in commercial flying in Europe since the armistice, and some of the notable work in this country, author tabulates present status in various countries. He starts with France, and this is concluded, although the article is not. The tabulated figures accompanying the text give all the general available data on the subject, such as number of routes, number of planes flown, number of pilots, miles flown, horsepower of flying units, etc. W. KNIGHT, *Aerial Age Weekly*, 3-20-22, 5700 w. MAH.

Reducing Road Wear through Tires. After going over the general transportation situation, this author, engineer for one of the largest tire concerns, points out the tremendous importance of tires, and the consequent advisability of conserving them. Then he proceeds to point out a number of ways in which this can be done. He favors the use of giant pneumatics under certain conditions, and the use of four rear wheels to make this feasible under very heavy loads. E. W. TEMPLIN, *Power Wagon*, 5-22, 3200 w. MAH.

Scheduling Work in the Repair Shop. Too much car and truck repair work is handled hit or miss, with consequent high costs, and dissatisfaction all around. This article points out that such work can be analyzed and scheduled so as to pass through the well-equipped shop just as quickly and economically as production work does through the small jobbing shop. He suggests advance estimates on all jobs, no matter how small; foreman planning work ahead for men and machines, and the use of a schedule board for showing present and planned work for each man and machine, at a glance. Not too technical, no suggestion of time studies or other involved and expensive methods, just a simple plea for common sense in a rather difficult business. J. H. RADEBAUGH, *Commercial Car J.*, 4-15-22, 3200 w. MAH.

High Cost of Service. Selling trucks will ultimately settle down to a question of service, and this author points out that fact, following it up with a description of a number of truck service stations. These might be classed as good, bad and intermediate, so that they represent all of the present phases of this situation. Reasons are given for present high costs, and concrete examples are presented to show how these may be reduced. Proper equipment is outlined for various sized service stations, and proper methods of using it. Of interest to the truck manufacturer, truck dealer, service station manager or owner, and to a certain extent, to truck owners. C. P. SHATTUCK, *Commercial Car J.*, 4-15-22, 2,900 w. MAH.

Wright Six-Cylinder Airship Engine. Technical description of this new design which has a 7-in. bore and an 8-in. stroke, developing 400 h.p. at 1400 r.p.m. and weighing but 3.3 lbs. per h.p. It is an entirely new design and is quite different from the Hispano previously built by the Wright Company. Said to have been designed for 100 hrs. continuous running at full throttle, which calls for very rugged construction, and accounts for the weight of the engine. *Aviation*, 5-1-22, 1000 w. MAH.

Stockkeeping System to Aid Efficient Service. The cry of today from car and truck owners is service, many putting service of the highest efficiency above the actual design and construction of the car and truck. The author describes the very thorough system devised for and used in the seven branches of the Packard Motor Car Co. of New York, and by its twenty-nine dealers. Forms are shown and their use described. PHILIP H. SMITH, *Automotive Industries*, 4-6-22, 3600 w. MAH.

Improved Method for Designing Aircraft Parts. Because of the extreme irregularity of airplane ribs, struts and other parts, the determination of the neutral axis, radius of gyration and moment of inertia is difficult, laborious and time-consuming. Yet because of the importance of these quantities, they must be determined with considerable accuracy. The authors have worked out practical method of doing this; that is, working out the neutral axis, radius of gyration, and moment of inertia graphically. It

BUILDING CONSTRUCTION

Lower Freight Rates Mean Lower Prices

IT is believed that the present freight-rate decision will give an added impetus to the building boom that is now under way. Lowering of the rates is expected to have a favorable effect upon material prices, which have been mounting skyward for the last few months. While the price of lumber is going up at the mills, the saving in freight may offset the increase in price. The cost of sand and gravel, in which transportation charges play such a large part, is also expected to be lowered. And on some materials where the price is largely determined by production costs, the price will be decreased if the produc-

tion cost depends upon the transportation of raw materials. Portland cement, which belongs to this class, has increased in price because of the excessive rates on the materials from which it is manufactured.

The American Contractor points out that the stabilization of material prices is essential to the continued prosperity of the construction industry, for while necessary building is not likely to be halted by high prices, speculative building is almost certain to be retarded while prices of materials are on the upgrade.

Design of Safe Construction—Reinforced Pressure Tank. Reinforced concrete used to an increasing extent in construction of tanks and reservoirs. In most of designs all tensile stresses are resisted by reinforcing steel, while concrete serves to hold steel in place and provides impervious walls for the reservoir. Stress of 10,000 lbs. per sq. in. necessary to secure water tightness. Hoop tension of side walls, soil pressure and air pressure important considerations. Tank must have tight upper base firmly fixed to walls. Flat, circular slab best for purpose; should be fastened to walls by means of vertical reinforcement. J. F. MANGOLD, *American Builder*, 5-22, 2500 w. HHH.

Nebraska State Capitol. Article describing some details of planning and ornamentation of building. It is 437 ft. square, two stories high with interior court. In center of court is cross-shaped executive building with tower 80 ft. square and 400 ft. high. BERTRAM G. GOODHUE, *American Architect*, 5-10-22, 4000 w. EMCC.

How to Build for Steel Sash. Standardization of sizes of steel sash by various manufacturers so that any standard construction method can be applied interchangeably to different makes has increased use of steel sash on small

(Architectural Forum)

construction jobs. For factories, school buildings, public buildings, etc., standard steel sash is mainly pivot type. As a rule, this type of sash does not call for separate steel framework, but is set directly into walls, reducing cost of construction, but emphasizing necessity of constructing walls properly to receive sash. *American Builder*, 5-22, 2000 w. HHH.

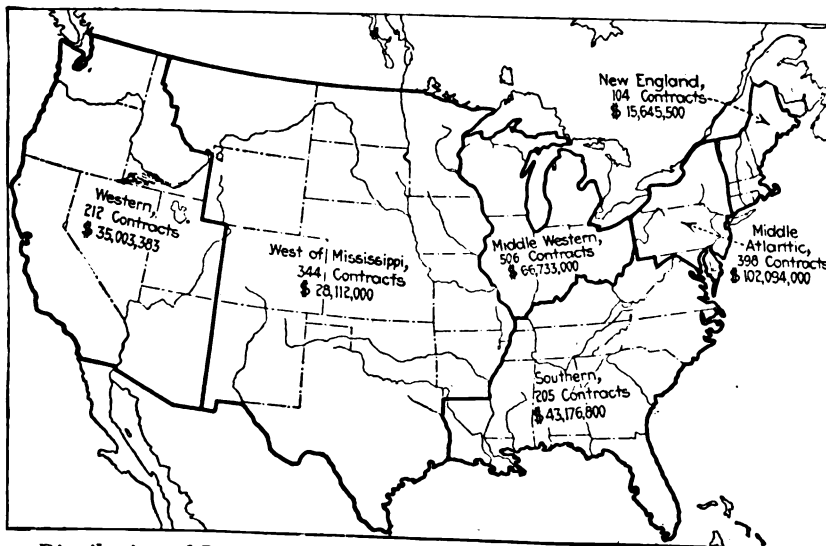

How to Kill "White Ants." In order to prevent white ants from damaging buildings, foundations should be entirely of stone, brick or concrete, including pillars in basement or cellar. Walls, partitions and flooring on ground floor, basement or cellar should also be of concrete. Wooden flooring can be laid over this concrete floor if more desirable. Air space should be left between concrete floor and wooden floor laid over it. Concrete floors should be laid on gravel base, which will prevent dampness and cracking. Points of juncture between concrete walls and flooring should be filled in by rounding off concrete at these places, since cracks often occur where wall and floor join at right angles. Where stone or concrete foundations are impracticable, timber impregnated with coal-tar creosote should be used. *Retail Lumberman*, 5-22-22, 1500 w. HHH.

Stanford Stadium Built of Timber on Earth Fill. Athletic stadium recently completed for Leland Stanford, Jr. University, embodies unusual design and construction features. Outstanding features are: (1) use of timber in seating structure instead of concrete, (2) placing of embankment by scrapers to form support for seat structure, (3) speed with which built, (4) skill and efficiency in prosecution of work. Article covers: general description, embankment, grading methods, soil investigation, timber structure, framing seating structure, horticultural features, drainage, cost. E. E. CARPENTER, *Eng. News-Record*, 5-4-22, 2000 w. CS.

Use of Explosives in Road Building. Very comprehensive article covering various explosives and proper use. Covers: blasting stumps, removing trees, blasting boulders, post holes, earth and rock excavation, rock cuts, ledges, etc. *Highway Engineer and Contractor*, 5-22, 4000 w. CS.

Record of New Building Permits in 19 Cities, Excluding New York, Over 20 Years, Showing Value of Permits Compared with Estimated Normal.—(*Architectural Forum*.)

Architect's Agreements with Owner. Misunderstandings which threaten to develop into legal proceedings often result of failure to establish proper agreements covering such specific questions as following: (1) In case architect is retained to design building on which owner has already given specific cost limitation, what is legal position of architect if it is found that cost runs considerably over figure when bids are taken? (2) How much of fee can architect collect in case building project is abandoned? (3) What is architect's position in matter of collecting fees if construction is unreasonably delayed? (4) What is architect's position when building project is transferred from promoter to another owner? Discussion of fees and methods of payment may be approached from viewpoint of mutual protection, so that no owner will hesitate to enter into proposed agreements. Three methods of meeting situation include (1) Determining amount and time of payment by verbal agreement with owner. (2) Establishing contractual relationship in letter form. (3) By use of properly executed contract between architect and owner. C. STANLEY TAYLOR, *Architectural Forum*, 5-22, 4000 w. HHH.

Study of Construction in Architectural Education. Theory of construction valuable to student in designing structural work of ordinary buildings, in consulting with engineers, in supervising construction and in giving him qualitative sense of construction. Teaching of design and drawing develops only one side of student's nature; study of building construction demands continual use of imagination in visualizing problem and continual use of judgment in evaluating elements which affect it. By working out structure of problem in design, student gains not only ability to design a beam, but sense of real forms with which he is dealing. CHARLES W. KILLAM, *Architectural Forum*, 5-22, 1500 w. HHH.

Elevator Installation. In laying out elevator installation, one of first things to be determined is speed and load. Under generally accepted regulations passenger cars are figured at rate of 75 lbs. live load per sq. ft., while cars to carry freight are figured at capacity determined by purposes for which they are to be used. Speed of car determines size of machine; when arranging for overhead work this must be taken into consideration. Elevator contractor should be furnished special $\frac{3}{4}$ -inch scale sketches showing general conditions ex-

isting around elevator shafts. From these sketches, drawings showing general arrangement of elevator installation can be made by contractor, which should be approved by architect. Pit in connection with shaft is of prime consideration. In majority of cases, with exception of traction drive elevators, depth of pit of at least 3 ft. 6 ins. from lowest stop to bottom of pit should be allowed. Waterproofing of pits and machine rooms where they are built in connection with pits, necessary. HERBERT M. GARRIOTT, *Architectural Forum*, 5-22, 2700 w. HHH.

Structural Design Problems. Editorial on subjects of restraint, continuity and unbalanced moments in designing beams, girders and slabs. Treats subject completely and in simple language without mathematics. Presents practical, graphical method and discusses a problem which was solved by its use, where the neglect to consider continuity had been costly for a school board. *American Architect*, 5-10-22, 3000 w. EMCC.

Country House in the Italian Manner. Description of house along Italian villa lines, but adapted to American environment. MATLACK PRICE, *Architectural Record*, 5-22, 1500 w. CS.

Small House Service Is Growing. Gives plan of American Institute of Architects to assist small house builder, through their Small House Service Bureau. Plans on file of two to six-room dwellings, with complete details, including quantity survey. Local and district agencies being established throughout country. Plans purchased from architects at regular prices, and retailed at small cost to home builder. Purchaser entitled to question service. EDWIN H. BROWN, *Construction Economics Edition, Amer. Contractor*, 4-29-22, 3500 w. CS.

Building Material and Construction Costs. Part X. Covers roofing material, with costs and other data—tin, galvanized, copper, zinc, formed rolls. THEODORE F. LAIST, *Construction Economics Edition, Amer. Contractor*, 5-6-22, 2500 w. CS.

CEREALS • MILLING

Europe Still Needs Our Wheat

ACCORDING to Dixie Miller, it will be necessary for this country to produce 800,000,000 bus. of wheat as a minimum in order to meet world requirements. While the visible supply in the United States remains large, it is pointed out that farmers are liquidating, farm reserves are not large and we have already exported more wheat than our theoretical surplus. Although Argentina and Australia have made heavy shipments for several weeks, and have considerable yet to ship, the wheat afloat only equals four or five weeks' supply.

Europe is still under the necessity of buying large quantities of foodstuffs before the new harvest is available and the world carryover at the end of the crop year on July 31 will

surely be small. To meet European demands it will be necessary to produce 600,000,000 bus. of winter wheat and a minimum of 200,000,000 of spring wheat.

While at present predictions in regard to the winter crop are premature, the winter kill appears to be no more than usual, while eastern Kansas and the States east of the Mississippi are reported to be showing up well. The danger spots are said to be western Kansas, Oklahoma and the Texas Panhandle. Up to the first week in March drought had prevailed since last autumn, when the wheat was seeded in dry soil, and although, with ideal weather conditions, a considerable crop might be harvested, the probabilities are against it.

American Flour in Levant. Two difficulties confronting importer of flour into Greece: unfavorable situation of Greek exchange; difficulty of buying remittances to pay for imported goods. In introducing flour in this market much depends on ease with which brand may be popularized. Many buyers and consumers do not understand English wording, so brand must be recognized by some feature of design. Constantinople not likely to offer permanent market for American and Canadian flour, but at present time from 10,000 to 12,000 tons each month are imported into city and probabilities are that requirements for next three or four years will be large. C. F. G. RAIKES, *Northwestern Miller*, 5-10-22, 4000 w. HHH.

Power and Lighting Economies in Bake Shop. Carelessness in handling machinery or in maintaining it in proper working condition are two greatest causes of excessive power demands. Improper arrangement of lights, unnecessary use of lights, or dark, heavy painted interiors increase cost of lighting service. Installation and arrangement of equipment have permanent effect upon consumption of power, hence care should be taken in laying out plant to avoid unnecessary complication in transmission system. Machine friction or resistance big factor in power consumption. Machinery should be properly lubricated and shafting and machinery should be in perfect

Domestic Exports of All Cereals and Products.

alignment. In every belt-driven installation, great amount of power is lost by belt slipping, this loss varying from 2% to 20%. To be efficient, belts should be kept tight enough to prevent more than 2% of slippage. When machine is driven by individual motor, care should be taken to see that driving motor gear is running in proper mesh with driven gear, or that chain belt is running true and with proper degree of tension. Electric motors must be kept clean and well oiled. *National Baker*, 5-22, 1800 w. HHH.

Underbolting. Wide divergence of opinion upon amount of bolting surface required for removing flour made by rolls. Since wheats milled are of varying degrees of hardness, bolting surface required on any mill will vary according to hardness of mill blend. Much harm may result to stocks of mill by causing product of rolls to pass over more sifting surface than necessary. Particularly true of heavy material sifted on wire, such as scalps of breaks. Greatest danger is carrying flour with middlings to next roll. Fine, bluish white product of reduction inferior in every way to material that has been reduced only just enough to allow its passage through meshes of proper flour-cloth. Although flour may appear more specky it will carry lower percentage of ash and higher percentage of gluten. Miller who must depend wholly upon ability to judge flour by appearance often misled by superior dress and apparent whiteness of product of underbolting. Usually requires physical and chemical analyses, and baking to ascertain why a flour fails to produce satisfactory results. E. S. MILLER, *Dixie Miller*, 5-22, 1200 w. HHH.

Quality Bread. High standard quality loaf should not be too sweet, of fair expansion, good interior development, creamy white in color, have appetite appealing flavor, be well baked, and devoid of soginess. Prolonged fermentation certain to result in excessive invisible loss for both sponge and straight dough. Correct fermentation means making dough with proper hydration, and at minimum point of viscosity, carried on at low temperature so as to obtain maximum baking value from all material used. J. E. WILLFAHRT, *National Baker*, 3000 w. HHH.

Static Electricity in Flour Mill. Dust fires often caused by presence of static electricity. Fires and explosions often started from such slight causes as exciting of static sparks when pouring gasoline from one vessel, not properly grounded, into another. Every exciting cause of electricity in flour mill should be well grounded, particularly all machines which have iron frames. Extreme caution necessary to avoid danger. *Dixie Miller*, 5-22, 1500 w. HHH.

Chart Showing the Gradual Increase of Dockage Found in Spring Sown Wheat from 1903 to 1920.—(Grain Dealers Journal.)

CLOTHING GARMENTS

Men's Clothing Prices May Advance

AN advance in the price of men's clothing is predicted by the *Manufacturing Clothier* as a result of the impetus that has been given the industry by new styles both in cloth and in the cut of garments, the better outlook for business, and, lastly but most important, the tariff.

It is believed that the placing of a duty of 33c. a pound on raw wool by the Senate Finance Committee will tend to bring about a considerable price rise in the clothing industry. A duty on raw material, unlike a duty on the finished product, increases costs all along the processing line. Moreover, this duty will bring up the cost of domestic raw

Pongee. Dry cleaning is not satisfactory with pongee. Hard brush injures fabric; best run in washer with good benzene soap; after drying wash with soap bark or tetrapole solution, rinse with acetic acid. Use a sponge. In spotting learn cause of stains as often steaming will remove. Seldom necessary to bleach pongees, instead treatment with potash and sulphuric acid. Best bleacher for delicate shades is hydrogen peroxide. Add little bluing if bleach is not sufficient. In dyeing, best results obtained by two baths; to bottom direct colors, to top with acid colors, with addition of formic acid. All dyeing with substantive colors can be topped with basic colors, but there is danger of cracking and unevenness. Pongees should not be sized, if finishing is done damp. **JOSEPH LOEBL, Textile Colorist, 5-22, 800 w. MBB.**

The Life Story of Flax. Flax is said to be known in stone age, from excavations of lake dwellings in Switzerland. Cultivated very early in Egypt, Mesopotamia, Persia. Used in England, 1532; in America, at Plymouth, Mass., 1639. Much waste in method of cultivation then; straw left from separation of seeds from stem always burned. **MRS. CHETWOOD SMITH, Fibre and Fabric, 5-2-22, 600 w. MBB.**

Scouring Rugs and Carpets. Method of recording order and of collection and delivery outlines. After dusting in wheel or by less vigorous ways in case of suspicious rugs, spots are removed and small repairs made. Scoured on table or floor with revolving brush working in soft soap of rather heavy consistency, then rinsed, scraped and dried. If tendency to change color is noted, weak acetic acid bath brings back color. Open-air drying most satisfactory. **E. A. TABOR, Cleaning and Dyeing World, 5-22, 1000 w. CJW.**

Nibs and Lousiness in Dyed Silks. Lousiness is caused by silks with low cohesion; affected by temperature of water, speed of reeling, cross or croisure made during spinning, clean-

material to the cost of the imported material.

It is not probable, however, that the effect of the tariff will be reflected until the fall season is under way, since clothing manufacturers have covered their requirements for the opening of the season on cloth bought at the low levels made by the textile mills early in the year.

Since the textile industry in this country uses about 60% foreign wool and only 40% domestic wool, it is estimated by the *Manufacturing Clothier* that of the anticipated increase of \$360,000,000 a year in the clothing bill of the nation, only about \$45,000,000 will go to the American wool grower.

ness of water and mineral salts in water. Nibs are only defect made by worms. Raw knots, corkscrews, large knots and loops are made during spinning. Diseases of silk worm do not seem to cause more nibs or splitting of fiber. Nibs are not made in dyeing operations but are developed by improper dyeing manipulations. Visibility of nibs is lessened when silk is dyed black and is greatest in yellow. **L. C. LEWIS, Am. Dyestuff Reporter, 5-8-22, 500 w. CJW.**

Developed Dyes in Hosiery Dyeing. Application; list of direct cotton colors that permit of diazotization and developing; list of developers and how to use them; list of shading dyes; and use for silk. **J. F. SPRINGER, Textile American, 4-22, 6000 w. WRR.**

Woolen Blanket Manufacture. Methods of making fancy blankets. White blankets with borders; traveling blankets; binding double fabrics; fringes add to appearance, Pullman blankets. **Textile World, 4-8-22, 3000 w. WRR.**

Tin Weighting in Silk. Description with charts of a practical analytical method for this determination. Ash determination; specific gravity; chemical stripping of weighing materials. **A. A. COOK, Textile World, 4-15-22, 2500 w. To be continued. WRR.**

Hat Talks. Third of a series, this instalment discussing price as a factor in sales. **FRANK BEATTY, American Hatter, 4-22, 900 w. WRB.**

Retail Direct Advertising. Persistence and continuity essential to success. Aim of direct advertising should be clear in mind of advertiser—whether it is to be for sales, inquiries, good-will, etc. Strength of appeal may depend upon copy, illustrations, type, unusual paper used for mailing or combination of one or more of these features. Securing a "live" list essential to success of direct-mail campaign. **ROBERT E. RAMSAY, National Retail Clothier, 5-22, 2000 w. HHH.**

Imports and Exports of Cotton Hosiery from January 1, 1921, to March 1, 1922. Black Bars Represent Imports, Shaded Bars Represent Exports.—(Underwear & Hosiery Review.)

DRUGS & CHEMICALS

For and Against the Dye Embargo

ACCORDING to *The Analyst*, the most important facts in the controversy over the proposed selective embargo for the dye industry are: (1) The charges of monopoly and combinations against the American industry have died from failure of proof. (2) As there seems to be no objection to high tariff rates, the method of protection has narrowed down to a question of an embargo of high ad valorem and specific duties. The advocates of the selective embargo base their arguments on the following points: (1) Germany, having had a complete monopoly of the industry for 50 years until the beginning of the war, enjoys the advantages of (a) having experienced chemists, (b) low manufacturing costs, (c) the condition of foreign exchange, (d) the demand of the world market for her products; (2) There are more than 200 plants engaged in the manufacture of chemicals and dyestuffs in this country, each in competition with the other; (3) Official comparative prices show the ability of the German manufacturers to manipulate export prices in order to overcome high tariff rates; (4) the possibility of being again dependent

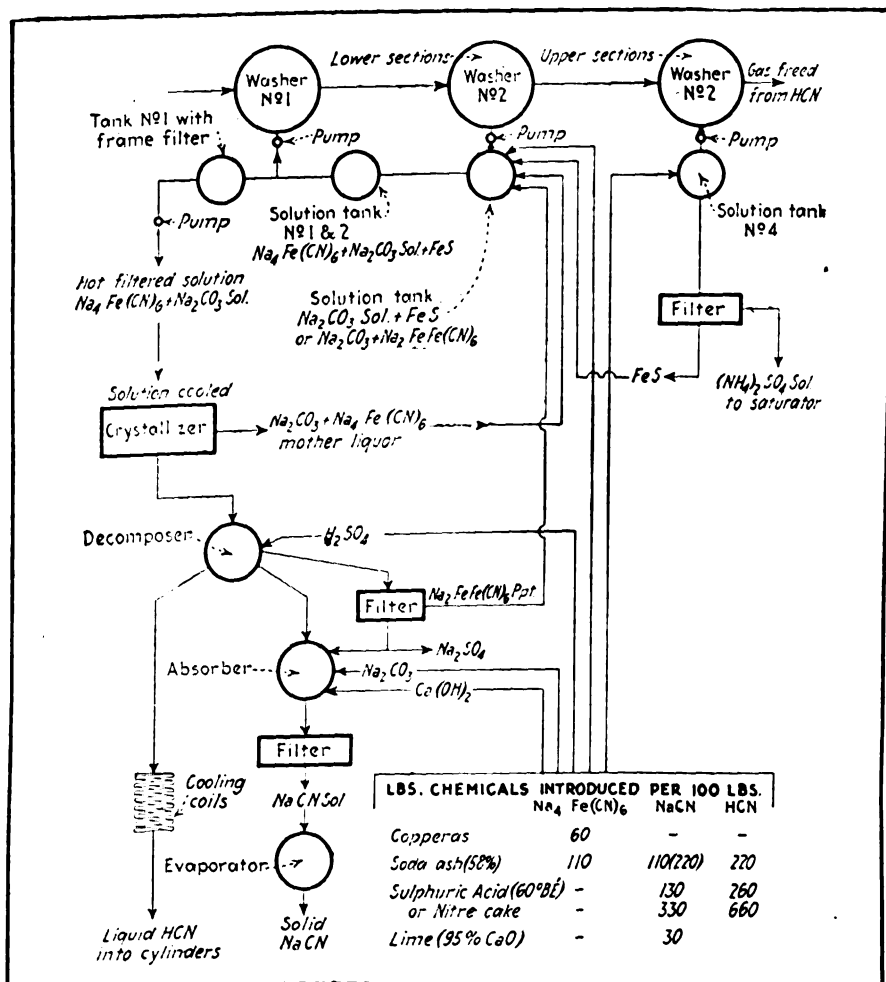

on a foreign country for dyes, chemicals and pharmaceuticals.

The arguments of the importers and those consumers who have not objected to strong tariff protection, but have fought the selective embargo, may be summarized as follows: (1) It is asserted that the delays incident to determining whether or not a similar American product is suitable for certain purposes often causes consumers loss of business. (2) Manufacturers using dyes claim that if they are not permitted to obtain the German product for certain purposes they will be handicapped in their fight against foreign competition. (3) It is held that the dye and chemical section of the Bureau of Imports is incompetent to judge as to the relative merits of foreign and domestic colors. (4) With respect to pharmaceuticals, it is argued that physicians should be permitted to buy the product in which they have most confidence. (5) The claim is made that if American manufacturers would write off their losses, due to depreciation of value of their warehouse stocks, they would be able to meet foreign competition with the protection afforded by the tariff rates.

Cyanide from By-Product Coke Ovens. Cyanogen compounds available in American coke oven gas are adequate to supply our entire demands. Ordinary uses of cyanides are: extraction of gold and

silver from ores, generation of HCN for fumigation of fruit trees, etc., case-hardening of steel, electroplating, and miscellaneous uses, such as synthesis of dyes. New process of recovery described

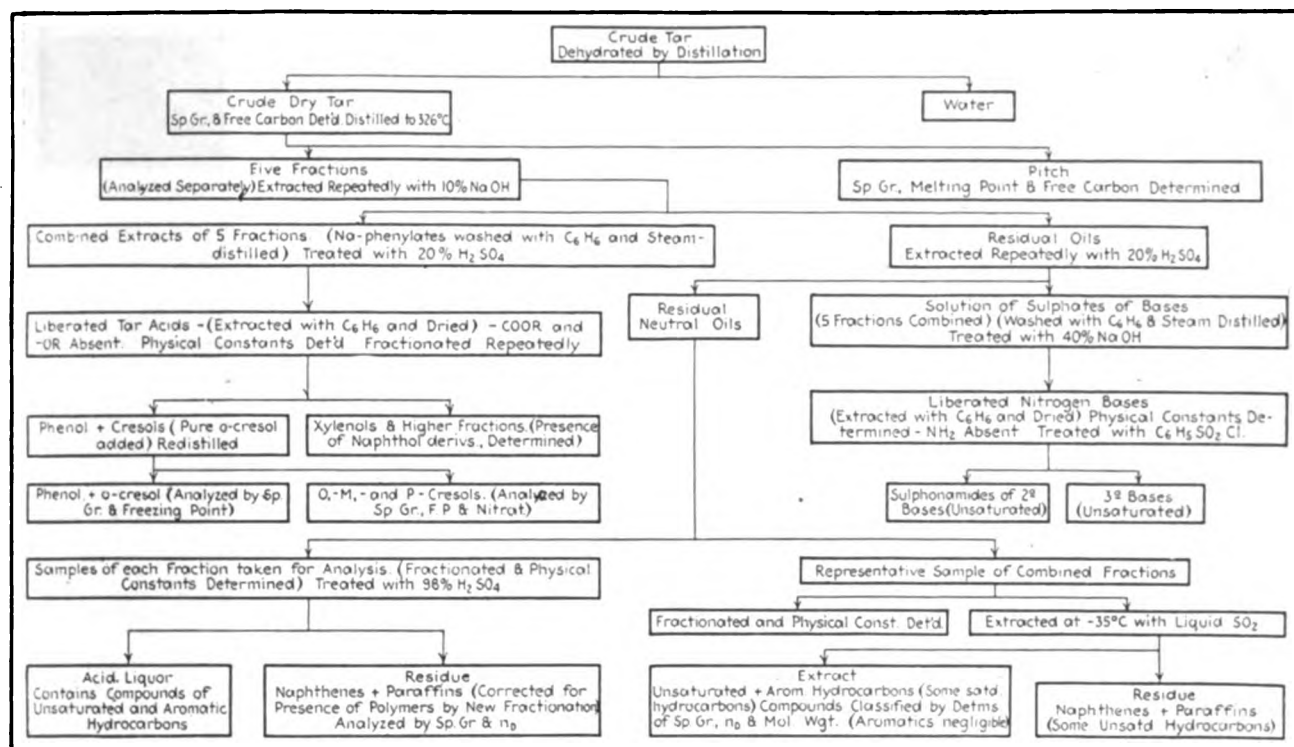

(see flow-sheet) based on washing with strong solution of alkali in which is suspended an iron compound, capable of combining with HCN of gas, which is recovered as sodium ferrocyanide. The crystals are treated with sulfuric acid, liberating half the hydrocyanic acid. Estimated price of HCN is 9 to 13 cents per lb., as compared with 30-50 cents for synthetic product. E. V. ESPENHAHN, *Chem. Met. Eng.*, 5-17-22, 2000 w. CJW.

Flow Sheet of Process for the Direct Recovery of Cyanogen Products from Coke-Oven Gas.—See Digest, "Cyanide from By-Product Coke Ovens."

Alunite Deposits in the United States. This little-known but very valuable mineral is the basis of much of our potash, aluminum and sulphuric acid, also of alum, refractories, abrasives, and, to a smaller extent, of the sulphate chlorate formate acetate bromide and chloride of aluminum. Perhaps the largest deposit is in the Tushar Mountains, Piute county, Utah, at an elevation of 10,000 ft. This was found while prospecting for gold, 12 years ago, and has been mined on a large and growing scale ever since. The article describes the mines, the camps where the men live, the difficulties of getting the machinery and equipment up there, the topography of the ground, methods of mining, hauling, milling and shipping the products, and other interesting details. Many figures are given on production, exports and imports of potash, aluminum and other salts, sulphuric acid supplies and prices, and much other correlated data. R. H. TINGLEY, *Rock Products*, 3-25-22, 6,400 w. MAH.

Bleaching Agents. Comparison of hypochlorous acid and chlorine as bleaching agents leave no doubt that, considered simply as bleaching agents, chlorine is more active than hypochlorous acid. Active bleaching properties generally attributed to hypochlorous acid are for most part imaginary and not characteristic of pure substance itself. R. L. TAYLOR, *Am. Dyestuff Reporter*, 5-8-22, 2000 w. CJW.

Scheme of Examination of a Low-Temperature Coal Tar. See Digest—"Low-Temperature Coal Tar."

Low-Temperature Coal Tar. Outline shown in cut. Tars produced by "Carbo-coal" process, using Pa. bituminous coal known as "Pittsburgh Terminal." Yield, 225 lb. per ton or 11.3%. Composition of tar: phenols, 13.7%; bases, 0.524; alcohols, .0; hydrocarbons: paraffin, 1.6; naphthalene, 2.8; unsaturated, 13.4. Composition of phenol fraction shown in this table:

Component	Composition of the Low-temperature Phenols		
	Percentages by Weight, Basis of		
	Phenols	late	Crude Tar
Phenol	4.2	1.9	0.6
Cresols a.....	33.4	15.2	4.9
Xyleneol fraction ...	19.0	8.7	2.8
Higher homologs...	34.8	15.9	5.1
Pitch (acid resins) ..	8.6	3.9	1.3

Totals 100.0 45.6 14.7
a Ratio: 27% ortho-, 19% meta- and 54% para-cresols.
(To be concluded.) J. J. MORGAN and R. P. SOULE, *Chem. Met. Eng.*, 5-17-22, 2750 w. CJW.

Acidity of Nickel Depositing Solutions. Measurements have been made of hydrogen ion concentration of nickel-plating solutions. Cathode efficiency is increased either by raising current density of hydrogen ion concentration (pH) or both. Near pH 6, or above, current density has little effect upon current efficiency. In operating bath at comparatively low pH (high velocity), raising current density will help to compensate for loss in current efficiency. If operating at low current density, solutions of high pH must be employed to secure high efficiency. Below pH 3 and up to 5, gas pits and streaks, which are usually attributed to hydrogen evolution, are very

pronounced. Cracking and peeling of deposits are generally encountered in this range. Between pH 4 and 5.5, gas pits and streaks may appear, but are not likely to be pronounced, and cracking or curling is less common. Between pH 5.5 and 6.5 gas pits and streaks are only rarely encountered. Above pH 6.3, blistering, cracking or curling are again likely to occur, also "burning" of deposit near sharp edges. Significant that commercial baths have fairly constant pH of 5.7. M. R. THOMPSON, *Trans. Am. Electrochem. Soc.*, 1922, 25 pp. CJW.

Pharmaceutical Junk. Much old stock in drugstores, worthless therapeutically, or at least sub-standard, which it is contended has material recovery value. Because of comparative ignorance regarding composition of most pharmaceuticals it would be taking undue chances to mix old material with new. Recovery value limited to alcohol, if content is above 10%, possibly oils, which may be sold for soap stock or leather tanning, and a few costly and simple substances like quinine, morphine, codeine and similar products. Expense of recovery important item. J. M. FRANCIS, *Bull. of Pharmacy*, 5-22, 1200 w. CJW.

Explosive Plant. Description of Northern Explosives, Ltd., at Dragon, Que., which

has capacity of 5,000,000 lbs. of commercial explosives per year. Consists of nitrator, expense magazine, wet gun cotton store, and 3 complete powder lines at right angles to other units. All machinery specially built. Buildings of wood, with wooden floors covered with rubberoid up to about 18 in. inside walls, roof of wood with metal shingles. Wooden rails by each building, doors open outward, no steel locks, catches, etc., all corners rounded. Nitrator of Hough type, taking charge of 1500 lbs. glycerine and 9000 to 10,000 lbs. mixed acids. Denitration unit is included in "Red Area." General description of acid plants. *Canadian Mining Jour.*, 4-28-22, 2000 w. CJW.

Wool Scouring Wastes. Concentrated wool scouring wastes liquor so far made contain 42% moisture, 14% potassium oxide, 1.25% nitrogen and 14% grease. Fertilizer material made from this and another waste material on factory scale contains 6.5% water soluble potassium oxide, 6.1% total nitrogen, 3.4% water soluble nitrogen, 1.9% alkaline permanganate and 1% neutral permanganate in soluble nitrogen and 6.8% grease. This material is in excellent mechanical condition, may be easily handled in fertilizer mixing and grinding machinery and in addition is good dryer, with dark color and fine strong odor. F. P. VEITCH, *J. Ind. Eng. Chem.*, 5-22, 1000 w. CJW.

Wool Fast-Color Dyeing. Suggests value of vat colors; means great advancement to wool-fast-dyeing industry. *Textile Colorist*, 4-22, 1200 w. WRR.

Hard Water in Bleaching. Cause of hard water and two methods of water softening. WILLIAM B. NANSON, *Textile American*, 4-22, 1200 w. WRR.

ELECTRICITY

Principal Radio Broadcasting Stations in the United States

THE black circles below represent a 30-mile radius from broadcasting stations, and the shaded areas show the 100-mile range. This gives a general idea of the localities in which the greatest sales of short-range radio receiving apparatus

can be made. Vacuum tube sets, with various amplification equipment, can catch broadcast from stations 1000 or more miles away. This chart presented by courtesy of the *A. B. P. News*, published by the Associated Business Papers, Inc.

A List of Stations Sending Messages with Call Letters, Wave Length, Name of Controlling Company and Range.

- Anacostia, D. C., NOF, 350 meters.
 Atlanta, Ga., 4CD, Carter Electric Company.
 Austin, Tex., 5ZU, 360 meters, Southern Radio Co., 200-500 miles.
 Chicago, Ill., KYW, 360 meters, Westinghouse Co., 2,000 miles.
 Cincinnati, Ohio, WMH, 360 and 485 meters, Precision Equipment Co., 1,000 miles.
 Cleveland, Ohio, WHK, 360 meters, W. R. Cox, 300 miles.
 Columbus, Ohio, 8YO, 275 meters, State University, 700 miles.

 Washington, D. C., KQV, Doubleday Hill Electrical Co.
 Washington, D. C., White & Boyer, 1,000 miles.

Operation of Electrical Units. First of series, which will discuss principles of construction and operation of the various units of automotive electrical systems. This one starts with the elements, considering magnetism, then passes on to types of magneto magnets, and concludes with a series of questions and problems concerning these elementary principles. Designed primarily for the shop man, who should get much benefit from the series. J. R. BAYSTON, *Amer. Garage and Auto Dealer*, 4-22, 2900 w. MAH.

Electric Safety Lamp. Methods used by Bureau of Mines for testing lamps for approval. Increased use due to following facts: Reduce hazard of gas explosion and burns; increase miner's efficiency because of good illumination; reduce risk of fire in mine; reduce accidents from fall of rock, etc.; reduce haulage accidents and accidents in handling explosives; increases opportunity for escape after explosion; relieves miners' eye-strain and improves health because of purer air, always keeps cool, does not go out when overturned, easily cleaned, reliable. Flame safety lamp should be used in conjunction with electric lamps, in order to test for methane. Discussion of various types of lamps approved by Bureau of Mines. Table gives detailed data of different makes of lamps. W. G. BURROUGHS, *Coal Industry*, 4-22, 2500 w. CJW.

Simplified Automatic Substation Control. Description of the single unit substations which are economically located and equipped with new type of simplified full automatic control. These have proved to be of great advantage. Various apparatus used in these automatically controlled substations is described. Load is controlled without the use of resistances. The housing space required is very small and there is no basement necessary. Voltage drop was cut by one-third. V. E. THELIN, *Electric Traction*, 4-22, 6000 w. IG.

Practical Hints on Phantom Circuits. Discussion of the principles underlying the use of such circuits. The requisites of a satisfactory repeating coil are described. Practical application and maintenance. Repeating coil should have perfect balance, high talking efficiency, high ringing efficiency, high insulation and high resistance. R. V. ACHATZ, *Telephony*, 5-6-22, 5000 w. IG.

The Use of Slip-Ring Induction Motors and Synchronous Motors in Cement Mills. Description of the special type of motors that are used in the operation of the various machines in a cement mill. Special features of the design are indicated. H. W. ROGERS, *J. Am. Inst. Electr. Engrs.*, 5-22, 3200 w. IG.

Electric Locomotive for Chile Freight Service. Besides two types of passenger locomotives to be used on the newly electrified State railways of Chile, South America, two types of freight locomotives are to be used, one for heavy road service and a lighter form for switching. This article describes the two latter, the heavy unit in more detail than the lighter. These are combination Baldwin-Westinghouse outfits, the latter company installing the electrical and air-brake equipment on the locomotive firm's framework. They are to be put into ser-

The Present Use of Power in the Superzone

Each dot represents 10,000 horsepower, and therefore 25 separate power plants, as 79% of power plants are of less than 500 horsepower. It is proposed to provide power enough—in the form of electric current—for all these establishments from 273 stations electrically connected. Waterpower will be utilized from the Potomac, the Susquehanna, the Delaware, the Hudson and the Connecticut Rivers and their tributaries; eventually also from the Black River, the Raquette, the St. Lawrence, and from Niagara Falls. But most of the current will be generated from coal in those localities where coal is cheapest, and some existing plants will be utilized and enlarged.—(*Forbes Magazine*.)

vice on the main line between Santiago and Valparaiso, 116 miles long, and on the branch line between Las Vegas and Los Andes, 28 miles. The heaviest grade is on the latter, 2.25%, and 12 miles long. Dimensions, weight, assembling details are given and numerous illustrations and drawings show all these data. F. E. WYNE, *Electric Railway Jour.*, 4-22-22, 3400 w. MAH.

Electric Furnace Iron and Steel. In Treadwell, Alaska, cast iron is made more cheaply in electric furnace than in cupola. Analyses show that from all-scrap cupola-melted iron, electric furnace product produces metal of greatly reduced sulfur content. Factors affecting economy of melting and advantages of electric furnace in foundry practice discussed. Average power consumption for 25 consecutive heats of iron and steel, with 2-voltage control, shows saving of 75 kwh. per ton of iron and 42 kwh. per ton of steel when using dual voltage. W. E. CAHILL, *Trans. Am. Electrochem. Soc.*, 1922, 5 pp. CJW.

Solutions for Coal Industry Problems

IN the opinion of the *Gas-Age Record*, there are two solutions of the basic problems responsible for the frequent strikes in the coal industry. The first is the appointment of a bureau of coal economics authorized to collect and disseminate coal statistics of all kinds. The second is the application of engineering skill and scientific knowledge to the coal industry in order to secure the profits of the operators, insure a greater annual income to the miners and supply fuel at a lower cost to consumers. At the present time less than 200 lbs. on the average out of every ton of coal mined is converted into useful work, and it is pointed out that the coal

industry must follow in the steps of the meat packers and start to refine coal and save the by-products.

That such action may be forced by competition between operators after the strike is settled, is the belief of a writer in the *Black Diamond* who predicts that under present conditions only the most efficient operators will survive. He goes on to say that although the public wants lower coal prices it is to be questioned whether merely a reduction in miners' wages and freight rates on coal will prove satisfactory—in view of the other uneconomic practices in the industry that demand attention.

Smokeless Fuel for Salt Lake City. Installation of by-product plant of sufficient size to supply entire domestic demand of Salt Lake City for fuel is not economically feasible unless municipal legislation prohibiting production of smoke is obtained. By education and legislation consumers must be induced to pay \$3 more per ton for smokeless fuel than for ordinary bituminous coal in order to make carbonization plant success. Means which should be considered for alleviating nuisance are: sale of available supply of gas-house coke, briquetting coke breeze from beehive ovens at Sunnyside for domestic fuel, burning powdered coal where feasible, installation of semi-experimental 100-ton plant for low temperature carbonization and continuation of educational campaign to teach domestic consumers proper methods of firing native coal. G. ST. J. PERROTT and H. W. CLARK, *Reports of Investigations, Bureau of Mines*, No. 2341, 18 pp. CJW.

Coke-Oven Construction. Assuming proper selection of brick, advantages of silica brick for oven construction are: Resistance to corrosion where salty coals are coked; possibility of increased output because of higher thermal efficiency; greater durability, more particularly under high temperature coking conditions. When non-salty coals are used, satisfactory oven is obtained by use of either fireclay or semi-silica bricks under normal temperature conditions of present British practice. Salt, however, causes corrosion of both these types of brick. W. J. REES, *Coal Trade Bull.*, 5-1-22, 1500 w. CJW.

Refuse as Fuel. With increasing price of fuel, practice of burning shavings and other refuse becomes more important. Excess of air formerly used to blow shavings reduced efficiency of combustion. Draft necessary for coal too strong for shavings and resulted in blowing much of refuse up chimney. Result of tests indicate that coal should be burned by itself and shavings by themselves in special furnaces, always aiming to use smallest number of boilers that will handle waste. Safety of operation must be considered. Description of boiler rebuilt to provide means of burning shavings and refuse efficiently. EINAR WINHOLT, *Power Plant Engineering*, 5-15-22, 1200 w. CJW.

Injection and Combustion of Fuel-Oil. It takes experiments with solid injection and air-blast in marine Diesel engines. Author, prominent British naval authority, describes the earlier experiments, the conclusions drawn from them, and the final experiments which proved them. He mentions the fact that he has dealt altogether with the high-speed engine, but believes his conclusions applicable with equal force to the low-speed type. C. J. HAWKES, *Motorship*, 5-22, 3200 w. MAH.

British Oil-Cooled Car Engines. Description of two new English car engines which have the lubricating and cooling systems combined into one. The crankcase is carried up around the cylinders and a much larger amount of oil is used, and is forced around through the system at a very rapid rate. This serves the double purpose of cooling and lubricating, saves weight in many ways, and eliminates a number of parts. Originally designed for use on motorcycles, it has been found so successful that it is now applied to two and four-cylinder cars, and several large makers have taken it up quite seriously. Higher efficiency is claimed, lighter weight, lower cost of production and greater ease of maintenance, all factors which bulk up large these days. The article describes and illustrates several of the engines. M. W. BOURDON, *Automotive Industries*, 4-20-22, 2300 w. MAH.

Demonstration of Deutsche Werke Engine. This is a new Diesel marine engine of 950 shaft horsepower, manufactured at Kiel. It is of the 4-cycle type, with cross head, is single acting, direct reversible, has 6 working cylinders arranged in a line with two 3-stage air compressors. The latter are driven by rocking levers off the cross heads, and have the high-pressure stage at the bottom. The main cylinders have a bore of 19.685 in., a stroke of 35.433 in., and develop 1280 indicated or 950 shaft horsepower at 135 r.p.m. Other details are given of the design and construction, with working drawings and photos, also details of the 7-day test. *Motorship*, 4-22, 2150 w. MAH.

Thyssen-Holzwarth Oil and Gas Turbines. For years engineers and designers have worked toward a combination of the gas engine and the turbine, believing that the high speed of explosive gases is particularly suitable for turbine

use. The tremendous temperatures have been an obstacle, and there have been many others, theoretical and practical. Two forms are now being produced commercially, however, the French Armengand and Lemale, and the German Holzwarth. This article is concerned with the latter, as it is being constructed by the Maschinenfabrik Thyssen, Mulheim Ruhr. Author claims that this form is superior thermodynamically to the other, and further that it has surpassed the steam turbine, and tests now under way show a tendency to increase the efficiency and economy toward the standard of the gas piston engine of the Diesel type. The article describes and illustrates a number of the Thyssen-Holzwarth products, notably a 500-h.p., a 1000-h.p., and two 1500-h.p. units. PROF. W. SCHÜLE, *Motorship*, 5-22, 2100 w. MAH.

The Still Engine. The principle of design of the combined Diesel-steam plant is generation of power through use of oil consumed within cylinder for the down stroke, steam produced by heat recovered from exhaust gases through medium of re-generator or boiler forming supplementary source of power for use on up-stroke on lower side of piston. Fundamental principle is recovery of heat from waste products of combustion and utilization of that heat in engine itself for development of power. These engines give lower fuel consumption per brake horsepower, have lighter weight per unit of power and occupy less space than any other known type of heavy-oil engine. System may be applied to either 2- or 4-stroke internal combustion engines. Present paper considers only single-piston type working on 2-stroke port-scavenging principle. *Motorship*, 4-22, 1200 w. CJW.

An American Development in Large-bore Aircraft Engines. The newest product of the Wright Aeronautical Corp. is a six-cylinder engine having a bore of 7 in. and a stroke of 8 in. It develops 400 hp. at 1400 r.p.m. The engine weighs 1320 lbs. dry and the jackets hold 38 lbs. of water, so that the modern tendency away from extreme lightness is shown, this being approximately 3.3 lb. per hp., as compared with 2.2, which has been attained in the Liberty, and 2.1 in the largest Fiat unit. The article describes the engine thoroughly, giving large drawings and many photographs. HERBERT CHASE, *Automotive Industries*, 4-20-22, 2500 w. MAH.

Estimated Average Total Production Per Working Day of Bituminous Coal, Including Coal Coked.—(Retail Coalman.)

Measurement of Superheat. Use of superheat becoming more general wherever economy of steam-driven apparatus is considered. Measuring superheat not difficult. Ordinary mercury and glass thermometer commonly used, registering as high as 575° F. Above this, nitrogen-filled instruments are used. Metal bulb filled with mercury vapor used where permanent fitting is desired. Third type is electric resistance thermometer, based on increase of electrical resistance of certain metals with temperature. Thermometer should be placed so that readings will not be affected by heat radiated from boiler furnaces or by colder parts of machine. Thermometer ordinarily placed in thin steel cup or well partly filled with mercury or good mineral oil. Thread of mercury should come just above cork stopper if possible to avoid stem correction. B. O. SNYDER, *Power Plant Engineering*, 5-15-22, 750 w. CJW.

Commercial Development of Gas Uses. Campaign concentrating upon intensive development of use of gas for water heating. Possible that this may be used to fill in valleys produced by house-heating business during winter. Urges importance of selling only quality merchandise, Standard Gas Appliance Specifications being used. Aggressive sales policy backed up by equally aggressive advertising program is combination needed by industry. O. H. FOGG, *Gas Age-Record*, 5-20-22, 2500 w. CJW.

Distilled Water Ice Plant. Watch small items to avoid shut-down. Steam condensers first to be considered. Excess condenser capacity should be provided. Circulate just enough water to prevent condensers from blowing hard. Flat coils next demand attention. Water should leave these coils as cool as possible. Use cold water direct from wells or other source of supply. Every de-

gree water is reduced saves refrigeration. Steam out coils only when oil begins to show on water entering fore-cooler. Transfer of heat from water to ammonia is more effective in fore-cooler than in ice tank. Water line from forecooler to can filler hose should be insulated. A. G. SOLOMON, *Power Plant Engineering*, 5-15-22, 1500 w. CJW.

Synthetic Gasoline Process. It is claimed that only 5% of the crude oil is made into gasoline, while it is possible to convert 30% of it into motor fuel. Most important processes for the production of gasoline are vapor phase system, pressure distillate system, chemical methods and synthetical crude systems. By far the greatest possibilities are presented by the latter process in reducing operating costs. Three types of the synthetic crude system are indicated. Comparative costs of the different methods are given to prove contention that the synthetic crude system is the cheapest. Various precautions are pointed out that must be followed in the operation of a plant using this method. Apparatus used is simple and can be added easily to existing plant. R. CROSS, *Petroleum Record*, 4-22, 1500 w. IG.

Modern Blasting Methods. Explosives are placed in hands of specially trained men, whose duty it is to see that holes are properly drilled, loaded and fired. Permissible explosives have been developed by Bureau of Mines, so that almost any combination is now available. High pay encourages speed and results in increased dangers of explosion and production of very poor grade of coal. Selection of explosives of primary importance. Scientific instead of haphazard. Shot-firing supervision is necessary. Five systems described as modern. Advantages and disadvantages of these

given. Differences between black powder and of permissible powder, a high explosive, makes necessary to drill holes differently and sometimes to fire shots in different rotation. Also advisable to make some changes in loading and stemming of holes when changing. Permissible explosives have reduced accidents and make working in mine more pleasant. A. E. ANDERSON, *Coal Industry*, 4-22, 3000 w. CJW.

Utilization of Bituminous Coals. Examination of coal includes ultimate analysis, proximate analysis, microscopic examination in thin sections, solvent action, progressive carbonization, and extraction of resins by inert heating medium. In selection, coals of extreme composition respecting volatile contents should be brought within range of 20-30%. Process factors comprise heat and pressure control, atmospheric variations and control, type of distillate, its amount and temperature release, form and state of charge. Use of pressure more important on by-product side than on coking. Suction densifies coke. Form of charge important in determining conductivity and incidence of heating temperature required in relation to other factors. State of charge important, in that dry charges require slower heating, followed by more rapid, whereas vice versa with wet charges. Discussion of function of resin in coal. W. E. DAVIES, *Gas Age-Record*, 5-13-22, 2500 w. CJW.

GLASS POTTERY

Glass Required for Automotive Industry

THE increase in the production of automobiles is expected to have a beneficial effect upon the glass industry, according to the *National Glass Budget*. Plate glass, especially, will be in demand. Some idea of the quantity of plate glass that will be required this year may be gained when it is considered that the average requirements of each of the 1,800,000 automobiles to be manufactured will be 15 sq. ft. of glass—which would mean that 27,000,000 sq. ft. will be used in new cars alone. This does not provide for the large amount of replacement glass equaling about 20% of the original amount.

A large amount of glass will also be used for the various

types of lenses in the headlights and the danger and stop lights at the rear of the car. It is pointed out that the average instrument board has at least one circle of glass covering some indicator. Many of the larger types of cars have as high as five or six circles. A reasonable average would be three to every car, or 5,400,000 circles for the total to be produced in 1922. Also at least 8,000,000 small electric light bulbs will be required. A large number of mirrors will also be used, since in a number of the larger cities automobiles must be equipped with a side mirror to warn the driver of approaching danger.

Analysis of Scientific Glasses. In analysis of more complex glasses it is preferable not to work through series of operation with one portion of sample, but several portions and one isolated one, or groups of constituents by suitable methods, which results in greater accuracy without increasing time needed for complete analysis. For estimation of silica, alumina, iron oxide, zinc oxide, lime and magnesia, it is necessary to first eliminate boric acid, if present. After fusion of sample with anhydrous sodium carbonate, fused mass is treated with hot water and hydrochloric acid, as in analysis of common glass. During evaporation of silica, add methyl alcohol saturated with dry hydrochloric gas. Repeat with this reagent until boric acid is removed. Filtrate from silica is heated, and gassed with hydrogen sulphide to remove lead, arsenic and antimony, if present. Precipitate is dissolved in nitric acid, and lead estimated as lead sulphate. Filtrate, and precipitate iron and aluminum with ammonia, dissolve precipitate in hydrochloric acid and reprecipitate. Filtrate from hydroxides is acidified with formic acid and gassed with hydrogen sulphide, which precipitates zinc as sulphide. In the filtrate calcium and magnesium are estimated as usual. J. B. KRAK, *Glass Industry*, 5-22, 2000 w. MBB.

Need of Care in Handling Glass Melting Pots. Clay pots should be placed in cold patch arch, not into one which has just been emptied and walls of which are still very hot and will heat the pot too rapidly. Matter of heating up pots needs much attention. Pots should be brought to maximum temperature and allowed to remain there until an even temperature throughout pot is obtained. This temperature should be 2100° F. to 2200° F., but many pot arches never attain this temperature. Care should be taken that blocks do not set too close to pot at time of building up wall, so that flames may circulate about pot during melting and working periods. It is advocated that pots be placed in furnace, stopper removed and that blocks be built up on breast blocks, encasing entire pot, including hood, in furnace and left for 15 hours. HENRY W. HESS, *Glass Worker*, 4-15-22. AMC.

Warm and Cool Color. A simple classification of colors is warm and cool. Majority of people like warm color schemes in preference to cool, as red ray of light is sharpest, causing more intense reaction upon optic nerve. Success of color scheme depends on amount of color used. This is determined by appreciation rather than rule. Colors must produce harmony, no color standing out alone in the design. Every warm scheme should have enough cool color to balance and enhance warm colors, yet avoiding too definite feeling. MARIE RIGGINS, *Keramic Studio*, 5-22, 500 w. MBB.

Lacquer Ware. Origin of lacquer is obscure. Undoubtedly first used in China as a preservative. Made from sap of lac trees cultivated throughout southern and central China. Trees are tapped once every seven years; sap which is white hardens as comes in contact with air. Juice is ready for coloring and application after refining by heating and straining. Floating lacquer on article requires skill. Put on too thin produces wavering, uneven surface; too thick coat will blister. Number of applications and intervening polishings vary from three to eighteen or more. ALBERT W. HECKMAN, *Keramic Studio*, 5-22, 900 w. MBB.

Pots Used in Optical Glass Manufacture. For optical glass, porcelain type pot is better than fire clay pot because of its increased density, uniformity, low iron content. In porcelain pot, refractoriness sacrificed somewhat to obtain density. Cast porcelain pot is denser, less refractory than handmade pot of same batch composition. Great care required with cast pots to select pot batch refractory enough at desired melting temperature, yet dense enough withstand excessive attack from glass. The effect of chemical composition has not yet been fully established. R. J. MONTGOMERY and M. R. SCOTT, *Glass Industry*, 5-22, 800 w. MBB.

Window Glass and Its Glazing. Two things essential to perfect job sash glazing—properly primed sash and good putty. Covers various qualities of glass and best methods of glazing. A. ASHMUN KELLY, *Building Age*, 5-22, 500 w. CS.

The Glorious Glass of Venice. Though art of glassmaking came to Italy from other countries, record shows old Romans had famous glass factories early as 54 B.C. Examples of this early work still inspiration, as quality of work never has been equaled. Venetian blown glass, always renowned for beauty of form and color, began to assume great importance in fourteenth century; after sixteenth Venetians ceased to make enameled glass after Arabian style, but manufactured absolutely colorless, transparent glass, blown to thinness of a wafer, later coloring it. From 1500 to 1550 the art was at its height, followed by fall of Venetian Republic and slump in art. In 1850 revived, and Murano, glass center, became again leader of industry. PAGE EATON, *Gift and Art Shop*, 5-22, 1000 w. MBB.

Making Colorless Glass in Tank Furnaces. Selenium considered most suitable agent for eliminating harmful discolorations in production of colorless glass, added either in form of elementary material, or as salt containing selenium, such as sodium selenite or selenate, the last being rarely used. Decolorizing effect apparently due to influence of selenium, whether as elementary selenium or reduced salts. (Con'td.) *Glass Worker*, 4-29-22, 1000 w. MBB.

Cleaning Producer Gas without Washing. Feasible to clean raw producer gas, retaining sensible heat of gas, in addition to saving B.t.u. value of tar and volatile hydrocarbon. Possible accomplish this without additional operating cost by means of a gas equalizer and soot collector, developed to treat gas from bituminous coal. Advantages of installation includes 20% to 25% saving on fuel, increased, improved quality production, saving in gas valves, less brickwork, labor and repairs; less labor in cleaning out soot each week, more continuous operation furnaces. JAMES H. MATHESON, *Glass Industry*, 5-22, 700 w. MBB.

What Proper Control of Pot Furnace Conditions Can Mean. Saving of the life of furnace and far better quality of glass at all times is possible from absolute control of temperature of fuel in pot furnace in glass factories. HENRY W. HESS, *Glass Worker*, 5-6-22, 2000 w. MBB.

IRON-STEEL

Electric Cast Iron

THE future undoubtedly belongs to electric cast iron. Where the weight of castings made is small or where an especially high grade of iron is desired for perfect castings the electric furnace in the near future is likely to prove economical. The tendency in all fields is toward products which are more uniform and closer to standard specifications. Cast iron forms no exception. The well-known dephosphorizing and desulfurizing action of the electric furnace, especially with basic lining, and the high degree of fluidity attainable

simultaneously indicate that, other things being equal, an attempt *must* be made to render it available for the foundry.

The development of the electric furnace for cast iron is, of course, only in its initial stages, but the attractive possibilities of obtaining a high-grade product under easily regulated conditions will soon find a response in the efforts of designers and builders of electric furnaces, and the next few years are certain to see considerable development in this direction, paralleling the rise and development of electric steel.

Factors Influencing Sheradizing. Series of experiments made in which each of these factors was varied, while the others remained constant, so as to determine what effect each had on the results of the process. First, it was desired to determine whether different grades of iron will sheradize at same rate. Little difference was found in the rates of deposit at temperatures below 400 C. At 430 C. rates upon cast iron and malleable iron was greater than upon iron with lower carbon content. Very thick coatings of zinc metal were obtained on cast and malleable iron only at temperatures above the melting point of zinc and in dust rich in zinc. Experiments were made to ascertain the reason for the same. It was found to be due to the silicon content of the iron. Silicon induces the rapid growth, but it was not proven that cast iron free from silicon would not act similarly. Iron in the zinc dust up to 2% causes a slight increase in the rate of deposit. At 4% the rate is about the same as when no iron is present. Beyond 4% the rate falls rapidly and at 10% it becomes zero. Cadmium, antimony, and copper in the zinc dust cause slight increase in the rate of deposit. Aluminum and lead have the opposite effect. L. McCULLOCH, *Elec. J.*, 4-22, 4500 w. IG.

Selecting a Grinding Medium for Tube Mills. Now that the quantity of work done by ball and tube mills has become large, the smaller parts of the machinery are attracting greater and greater scrutiny as to their fitness for the work. This author takes up the selection of balls, deciding against cast-iron balls because of their brittleness, for steel balls because they hold their polished surface, and for forged steel balls for all-around results. Next he takes up the effect of mill speed on the wear of the balls, practical uses of grinding balls with reference to special shapes for special services, and other relevant matters. NEWTON L. HALL, *Rock Products*, 4-22-22, 1900 w. MAH.

Development of the Fluorspar Industry. This is one of the products emphasized by the war. Little known before, the great demand for steel, in which it is an important flux, and for acids caused and tremendous increase in its production. This article describes the

material, where and how it is found, how mixed or excavated, how it is milled or handled after being taken out of the ground, how it is screened and classified, and how sold. The author describes also the explorations for new deposits. Further, he argues for continuous purchases by steel makers, with the idea that a continuous or constant output would encourage and stabilize operations in this non-metallic mineral. J. M. BLAYNEY, *Cement, Mill and Quarry*, 3-22, 4100 w. MAH.

Change in Dimensions of High-Speed Steels in Heat Treatment. Change in length was measured. Tables show original length, as quenched, as drawn at 300, 500, 700, 900 and 1100° F. and as annealed. MARCUS A. GROSSMANN, *Amer. Soc. for Steel Treating*, 5-22, 1800 w. APS.

Synthetic Cast Iron. Production consists of melting steel scrap or combinations of iron and steel scrap, in acid or

basic electric furnace, with highly carbonaceous material (coke, oil still residue, etc.), to give necessary carbon content to iron, and making adjustments in percentages of manganese, silicon, sulfur and phosphorus to give desired characteristics in finished metal. Examples of charges are given, and also methods of adjustment of analysis. Quick testing method, using Brinell testing machine, has been devised. Has most useful field, in localities like Pacific coast, distant from fuel and pig-iron supplies, but with low power. Most immediate and logical application in production of castings. J. L. CAWTHON, *Proc. Am. Electrochemical Soc.*, 1922, 12 pp. CJW.

LEATHER

Lynn, Brockton and—St. Louis

IS the boot and shoe industry likely to follow the lumber industry and other important basic industries westward? A comparison of the conditions governing manufacture in the East and in the Middle West indicates that there are a number of factors favoring production in the Middle West. First, the Middle Western States are closer to the source of raw material. The Western hide markets are nearby and the hides imported from South America may be transported at much less expense up the Mississippi than by freight to the East. Tanbark and tanning extract are secured chiefly from South Carolina and other Southern States which are closer to the Middle Western production centers.

The position of the West in regard to markets is also advantageous. The center of population, once located near the Eastern seaboard, has moved until it is now in the locality of Cleveland.

Labor conditions are more favorable to manufacturers in the Middle West because there is a plentiful supply of non-union labor, while in Massachusetts and the New England States labor is strongly organized and wages are considerably higher. The cost of land and of building, both in regard to materials and labor, are also cheaper in the West, which makes for lower rentals and generally lower overhead costs.

Lime Liquor in Tannery. Application of theories of Proctor and Wilson and of Loeb to alkaline swelling of hide in lime liquors. Real reason why such "sharpening" agents as sodium sulfide and sodium carbonate produce greater swelling is that osmotic pressure of sodium collagenate is greater than that of calcium collagenate at the same hydrogen ion concentration. Smooth grain of skins unhaird by arsenic sulfide is due to fact that only calcium collagenate is produced. Alkaline swelling is shown to be exactly analogous to acid swelling,

Grain side to pulley is best for leather belting. See digest "Grain Side to Pulley. . ."

which has been much more extensively investigated, and certain tanning processes are shown to act in parallel way to acid pickling. W. R. ATKINS, *J. Ind. Eng. Chem.*, 5-22, 2000 w. CJW.

Grain Side to Pulley Is Best for Leather Belting. Method of making tests and results obtained. From data obtained there is no doubt but that there are distinct advantages in power transmission to be had from running leather belts with grain side to pulley. T. W. STEERE, *Fibre and Fabric*, 4-11-22. AS.

History of Conveying Belts. I. Story of development of the industry of conveying belts. The part Thomas Edison played in this development is told. T. ROBINS, *India Rubber World*, 4-22, 2000 w. IG.

Industrial Lighting. Defective illumination in workrooms and defective sight among workmen are jointly responsible for industrial waste of enormous total. Both of these factors are within control of modern employer. Their correction assures positive increase of production, and at disproportionately low cost, aside from humanitarian considerations. With all modern improvements in lighting equipment and eyeglasses, hosts of workmen are still laboring in semi-darkness. *Industrial Power*, 5-22, 1500 w. CJW.

The Trend in Heels. Higher heels are becoming vogue. Low heels manifested interesting psychology—the desire for feminine comfort and health, and the vogue among "flappers," who mostly demanded the "boxwood" or covered military, about an inch high. It is believed the future popular heel for street and evening wear will be about two inches high. Style change is slow; appears to be toward simplicity. *American Shoemaking*, 5-24-22, 1000 w. WRB.

Too Many Shoe Styles

IN the opinion of a writer in *The Shoe Retailer*, there is no profit for either shoe manufacturer or retailer in continuing to offer a wide variety of styles. The mere changing of styles will not influence people to buy more pairs of shoes, and although it may be possible for a few large city stores to operate successfully under this system, for the smaller dealers it means ruin, since their profits would be tied up in stock several months old and out of date.

Reducing the number of styles, however, does not mean that stores should return to the old "no-style" shoe days. Should such a policy be adopted, it is predicted that half the retail stores would close up and the other half pay only a living salary to their owners under present-day expenses. But both manufacturers and dealers must realize the uselessness of trying to play the style game with the same insistence during slack periods as in prosperous times.

The problem of handling style shoes profitably would appear to be one that must be solved by each individual dealer. According to *The Shoe Retailer*, the only safe course for him to pursue is to put aside a buying budget and divide it into three classes—staple, semi-staple and novelties—putting into the stock the right proportion of these three divisions, based on the line of customers he has established.

Leather Measuring Devices. Author reviews uses of leather; 681 leather manufacturers in 1920, with output valued at \$829,688,200. Largest number in Massachusetts. Of output about three-fourths, or 1,157,818,200 sq. ft., sold on area basis. Inaccurate measurement methods produced large losses to most manufacturers, showing need for measuring devices, which author describes. Test of ordinary measuring methods with use of accurate devices showed variance of approximately three feet per dozen skins. Article of much value to all leather producers. *American Shoemaking*, 5-24-22, 4500 w. WRB.

How a Richmond, Va., shoe man cuts 25 pairs of half soles from a single bed.—(Shoe Repairer).

Doing Business Blindfolded —and Its Awful Cost

THOUSANDS of businesses suffer from blindfolded methods—a continual groping for hidden records! And worst of all, many executives don't seem to realize the awful cost of this condition!

That was the case with a Cleveland firm. They had important records to which they referred continually, yet failed to realize the cost of handling them. A test under actual working conditions disclosed a tremendous loss of clerical time—40% of it totally wasted!

That condition is typical of thousands of businesses. The aggregate loss is enormous—unbelievable! Does that condition exist in YOUR business?

A good example of business records simplified through plain sight in a Rand Traco Cabinet. Every index item plainly visible, hence instantly located. Cards easily removed and returned to transparent faced pockets. More serviceable because easily seen.

MACHINERY

Automatic Machines Replace Hand Labor. Describes very intricate and equally interesting machines which have been developed by Bock Bearing Co., Toledo, O., for gaging and sorting the rollers used in Bock bearings. A single machine replaces 10 girls, and does work more rapidly and accurately. Machine is described in some detail. The company has also developed a grinding machine which automatically grinds the spherical head on the rollers, and takes the place of hand-operated radius grinders. Other machines and other phases of the work of producing these bearings are described. *Iron Age*, 4-20-22, 2800 w. MAH.

Examples Where Vertical Milling Saved Money. A number of pieces of work are shown and described, on which the vertical miller has made much better time than any other machine. Some of the others were boring mills, some shapers, some planers, etc. A single example will show: a cast steel electric motor bracket which required 55 mins. to finish on the boring mill was completed in 9½ on the vertical miller. The article goes on to show how work should be handled, how held on the machine, what kind of tools should be used, etc. It takes up continuous milling as well. J. H. MOORE, *Can. Machinery*, 4-30-22, 2100 w. MAH.

Cutting Production Time in Four. Study will adapt almost any piece, no matter how complicated to the automatic screw machine, and once the work has been adapted, the tools made and set up, and a long run started, the cost of production is certain to be materially reduced, that is to ¼ or less of the former cost. Author takes an apparently very complicated small piece, with several stepped surfaces, a deep neck, 3 different internal sizes with shoulders, etc., and shows how this was adapted for automatic screw machine work, and gives also specific figures how the time on this was cut down to its lowest possible limit. Also describes other similar pieces of work in the same way. J. H. MOORE, *Can. Machinery*, 3-16-22, 1700 w. MAH.

Practical Application of Precision Instruments. A continuation of an article, the first part of which was previously digested here. This part takes up the construction of various kinds and types of accurate gages, the idea being to show how they can be so accurate. Other sub-topics are improved design, increase efficiency, reducing weight of larger sizes, combining blocks for checking dimensions, testing micrometers for wear, checking jigs, snap gages, plug gages, ring gages, others. H. ALTON, *Can. Machinery*, 4-30-22, 3850 w. MAH.

Handling with Portable Conveyors. The title scarcely does the article justice, for in its scope it far outstrips the simple word "handling." The author describes the present field for all kinds of portable conveyors, and then describes the conveyors themselves, taking up all the well-known products now on the market, and their application to everyday work. In addition, he describes belt roller and similar conveyors, which are more nearly semi-permanent in nature than the ordinary loader or unloader. With the latter, he describes as well the usual sources of power, and some unusual ones as portable gasoline engine power plants. Scattered through the article are many hints firms not now using portables or belt conveyors could take with profit to themselves. E. J. TOURNIER, *Gas Age-Record*, 3-18-22, 4500 w. MAH.

Driving Chuck for Automatic Lathes. A certain automobile clutch gear was so difficult to handle that none of the ordinary lathe drivers or dogs were suitable. This man designed and constructed a special chuck for this purpose, and the article describes both the clutch gear and the driving chuck, as well as its method of use. E. M. BOWELL, *Machinery*, 4-22, 1300 w. MAH.

How a Big Publisher Saves Thousands of Payroll Dollars Annually

Pictorial Review Company, of New York City, is another progressive concern which has learned that it pays to buy shop trucks on the basis of what they save, not on what they cost.

Geo. E. Gavin, in charge of production, says: "Our Stuebing Lift Trucks enable us to use big stock piles and conserve storage space. They speed the moving of paper from department to department and are a real help in producing on scheduled time the more than 2,000,000 magazine copies we

print each month. *Without the Stuebing System we believe it would take forty men to do the trucking now done by ten men.*"

Whether handling flat stock, case or sack goods, heavy machinery or small parts, a Stuebing Lift Truck System will show savings that no factory executive can afford to overlook. At your request, one of our experienced shop trucking engineers will call and explain what a Stuebing System will accomplish in your plant.

One man rolls a Stuebing Lift Truck under a loaded platform, lifts it with an easy pull on the steering lever, quickly moves it to any location, and safely lowers it to the floor.

The Stuebing Truck Company, Court and Broadway, Cincinnati, Ohio

LIFT TRUCK SYSTEMS

LUMBER·WOOD PRODUCTS

Home-Building Good Furniture Barometer

ALTHOUGH the refusal of the retail dealers to accept inventory losses has been a serious handicap in the recovery of the furniture industry, it is believed that the industry as a whole reached the lowest point of its activity at the beginning of 1921. Since that time it has gained steadily, and a further improvement is expected as a result of the present boom in building operations. The great number of small homes that are now being erected is a favorable indication of increased sales. It is believed that influence from this direction will be felt by the first of August and that it

will continue into the early winter. Although the greatest demand will probably be for the medium-priced lines, it is expected that the sales of furniture will exceed those of last summer and fall by at least 50%.

While furniture has resisted the downward movement of prices in general more strongly than any other commodity and has caused buyers to purchase cautiously, it is believed that as prices of other finished materials hold firm, or move a trifle higher, it will be easier to convince the consumer that prices in the furniture industry are stabilized.

Port Orford Cedar and Selective Logging. Selective method of logging practised in cutting Port Orford cedar concerns community as well as timber and land owners and operators. Co-operation of owners and operators necessary to secure perpetuation of trees, because of varied relations of owners and operators and variety of methods of operating, as shown by following groups: (1) contractors or purchasers cutting Port Orford cedar for special use where only select trees or clear parts of trees are taken. (2) Contractors or purchasers cutting all of the merchantable Port Orford cedar, but leaving all other species. (3) Owners operating on their own land, either for special use or cutting all of the Port Orford cedar. (4) Purchasers of large timber tracts. Clearcutting the stand including all species. (5) Owners of large tracts of land and timber. Clearcutting the stand including all species. Danger to future of Port Orford cedar forest lies in selective cutting, because it removes all

cedar from stand and restocking of area depends upon seed in forest floor or in cones at time of cutting. Port Orford primarily a "specialty" wood; if so utilized would become most valuable species in Pacific Northwest. Dr. J. V. HOFMANN, *Timberman*, 4-22, 2800 w. HHH.

Use of Pumice. Pumice not a powerful abrasive. Virtue lies in perfection of finish produced, not in amount of abrasion. Among factors contributing to excellence, uniformity and purity take precedence over abrasive efficiency. If two samples of pumice produce same perfection of finish, deciding factor is speed. Abrasive efficiency of pumice may be determined by rapid rotation of metal rod imbedded in mass of powdered pumice. Loss of weight sustained by rod when rotated under known conditions is measure of abrasive efficiency of abrasive in which it is imbedded. LEO RATNER, *Furniture Manufacturer and Artisan*, 4-22, 1000 w. HHH.

Lumber Carload Minimum Weights. Decision handed down in "Lumber Carload Minima" case by Interstate Commerce Commission upholds contention of shippers that cubical capacity basis is unjust. Commission rules that interstate transportation of pine, fir, hemlock, larch and spruce lumber and articles taking Group D rates from points of origin in Oregon, Washington, Idaho and Montana to points of destination, designated in the transcontinental east-bound lumber tariffs, carload minima shall not exceed the following:

	Pounds
For cars 36 feet and under in length	38,000
For cars over 36 feet and not over 42 feet in length	44,000
For cars over 42 feet in length	54,000
When cars are loaded to full visible capacity charges will be based upon actual weight, not less than 30,000 pounds.	
<i>Mississippi Valley Lumberman</i> , 4-22, 1200 w. HHH.	

Hardwood Lumber Price Fluctuations, Quoted on Chicago Market

(From Furniture Manufacturer & Artisan)

How America's Leading Men Safeguard Their Health

By Frank G. Soule

FRANK G. SOULE

HOW many times have you picked up your morning paper and read something like this:

"Mr. John Smith, the well-known merchant, was stricken last night in his

home with an acute attack of ———. He died before medical aid could reach him. Mr. Smith's sudden and untimely death will come as a profound shock and tragic surprise to the entire community as he *apparently had been in the best of health!*"

Mr. Smith's "sudden" and appalling death got into the papers because of his prominence. But for every Mr. Smith there are thousands of men and women stricken, and snatched away in the prime of life, people whose "sudden" deaths are not of enough importance as "news" to be recorded.

And Mr. Smith *apparently had been in the best of health!* But as a matter of fact his death was not "sudden." Like hundreds of men in your very community are doing today, *he had been dying for years without knowing it.* Had he taken the same precautions with his precious human machine that America's leading men now take with theirs, he might have been spared for many years of healthful, vigorous life.

For it is true that always, for months, even years, there are unmistakable indications in every person's system which shows definitely and conclusively exactly what is wrong. But the pity of it is that the diseases which cause these "sudden" deaths in the prime of life, diseases that often carry off little children, almost in the twinkling of an eye, are so insidious in their attack that there is no outward symptom of their presence until the victim has passed beyond all hope of recovery. In fact, an alarming feature of these diseases is that the very poisons in the blood which cause such "sudden death" often give a fictitious stimulation which gives the victim all the appearance of good health; rosy cheeks, bright eyes and unusual energy. Yet all the time the body may be slowly but surely breaking down under the vicious influence of these unseen poisons.

Because there are 600,000 deaths in the United States each year from preventable

diseases—because there are 3,000,000 people sick all the time, most of them needlessly so—because many of these insidious diseases stimulate a fancied feeling of good health and energy—because there are no outward signs which show that the system is slowly getting to the point where "sudden death" is likely: It is for these reasons that America's big men have demanded some kind of efficient protection against the lightning-like death that strikes everywhere, everyday.

Fortunately there is a way to know when this unseen and unfelt disintegration has started, and there are many simple ways of checking the progress of the diseases and restoring the patient to perfect health. Science can warn you of approaching danger, protect you and your loved ones from these diseases and add, perhaps from ten to twenty years to your normal life span.

It is by the use of these scientific measures that America's Leading Men: such men as Wm. Wrigley, Jr., Carl Laemmle, President of the Universal Film Company, George Ade, the Famous Humorist, Chick Evans, the Golfer, Paul A. Harris, the founder of the Rotary idea, Justice O. N. Carter of the Illinois Supreme Court and thousands of other men at the heads of their professions—brokers, lawyers, judges, doctors, preachers, manufacturers, builders, contractors, publishers, editors and writers—protect themselves against, and have ample warning to ward off the slow disintegration caused by sedentary living, lack of exercise and high pressure brain work. These men—every ninety days—without leaving their offices and without spending more than four minutes each year, obtain the most thorough and complete analysis of their physical condition ever made and receive a detailed report showing exactly what may be wrong. In addition they receive a sheet of helpful suggestions for correcting the trouble and warding off the disease that might otherwise strike death into their midst, deprive their businesses of their guidance, their friends of their association and their loved ones of their protection.

A few years ago, such a service as this—by virtue of its cost and inconvenience—was out of the reach of most men. Only moneyed men could afford to undergo, at the hands of specialists, an examination which showed the exact condition of their bodies. But now, thanks to the corps of trained Scientists and specialists maintained by the National Bureau of Analysis this service has been put within the reach of every man and every woman and made available for every child at a cost which is insignificant when compared with the value of human life.

Send for Free Book on Health

Remember that personal appearance and a feeling of well-being are not always an indication of good health. Instead, the

WILLIAM WRIGLEY, JR., president of the company which bears his name, is one of the hundreds of leading American business and professional men who safeguarded themselves against serious illness and "sudden" death.

very feeling of good health and energy which you have today may presage a breakdown, possibly a long illness—possibly "sudden" death.

Do not live in a fool's paradise of fancied good health. Accept the friendly warning of an unbiased and unprejudiced organization such as the National Bureau of Analysis and find out at once what is really happening to your body, unknown to you. Send at once for our brochure entitled, "Why People Die Too Young." It will not obligate you in any way. No solicitors will bother you. You will not be urged to subscribe to the Bureau's Service. But with this booklet in hand you will be better able to tell exactly whether you need such a life-saving service as the Bureau offers and exactly what it can do for you. Show the brochure to your physician if you like. Get his opinion. Then even if you do not subscribe, the knowledge gained from a reading of this valuable treatise will be of inestimable value to you. Simply fill in and mail this coupon today.

NATIONAL BUREAU OF ANALYSIS, Dept. 56

METAL

Copper Is Going Strong

UNUSUAL strength has recently prevailed in the metal markets. Silver, steel billets and lead have reached high marks for 1922, and copper has advanced to a new high level, although not reaching the high price recorded early in January. The copper industry, which was the first to deflate after the war-boom, is recovering very strongly, and the heavy stocks on hand amounting to about 400,000,000 pounds, are about half earmarked for export by the Copper Export Association. Producers are now quoting 13½c and predictions are that the metal will sell at 15c per pound before the end of June, and 16c before September 1. The following table shows the highest and lowest prices quoted for copper over a series of years:

Date	Highest	Lowest	Average
1922	\$13.50	\$12.00
1921	14.00	12.00	\$12.50
1920	20.50	13.75	18.01
1919	24.00	15.25	19.49
1918	26.00	23.00	24.68
1917	36.00	23.50	29.18
1916	35.00	23.00	28.17
1915	23.00	13.00	17.64
1914	15.50	11.30	13.61
1894 (lowest) ..	10.25	9.00	9.43
1880	25.00	17.875	21.50
1875	23.875	21.50	22.69
1870	23.375	19.00	21.19
1864 (highest)...	55.00	39.00	47.00
1860	24.00	19.75	22.875

Losses in Smelting Low-Grade Lead. During war, Continental lead-smelting works were obliged to smelt poor materials like muffle residues, rich slag, mattes and impure low-grade concentrates. Accurate tests showed that charges with 11.41, 12.46 and 15.05 per cent lead gave lead losses of 17.39, 14.64 and 10.9 per cent respectively. Waste gases contained on average 0.732 grams of lead per cubic meter at 35° C., and it was calculated that 6 cubic meters of waste gases escaped per second. Of total loss during 3 weeks, 12.5 per cent went through stack and 87.5 was lost with slag. Clearly evident that in smelting materials poor in lead loss is mainly in slag and that in such operation, given good separation of matte and slag, most important thing is to make slag low in lead. Unavoidable slag losses will always be considerable. C. OFFERHAUS, *Eng. Min. J.-Press*, 4-8-22, 2000 w. CJW.

Blue Powder in Zinc Smelting. Figures of blue powder production show good deal of uniformity and indicate that blue powder product bears large proportion to ore originally charged into retorts; large proportion of retort capacity is devoted to redistillation of blue powder; about 30% of spelter product of furnace is derived from blue powder, i. e., it is zinc that has been distilled twice. European zinc distilling practice is better than American in matter of by-products. Attributable in large measure to European type of furnace front, with condensers enclosed in deep closets and to custom of drawing spelter only once in 24 hours. No criticisms offered. W. R. INGALLS, *Mining Metallurgy*, 4-22, 1500 w. CJW.

Aluminum-Silicon Alloys. Historical review. These alloys in general are quite resistant to corrosion, if iron content is low. They are machinable, but do not machine as well as standard aluminum-copper alloys. Use of processes to modify or disperse silicon is advantageous chiefly when quantities of silicon above 8% are used. Chief advantage of these alloys is in their casting qualities, which advantage is present both in normal and modified alloys. Iron makes aluminum-silicon alloys more corrodable and in general weakens and embrittles them.

Greater amount of silicon used, less is permissible iron. It is safe to predict that both normal and modified alloy castings will become commercially important. In modified alloy castings silicon should be from 8 to 15%. In normal sand castings silicon should be from 4 to 10%, according to requirements. ZAY JEFFRIES, *Chem. Met. Eng.*, 4-19-22, 3000 w. CJW.

Cooperite, Non-Ferrous High-Speed Cutting Metal. Nickel base alloy to which are added zirconium, aluminum, silicon, tungsten and molybdenum. Heat seems to increase cutting-edge strength of this alloy, which is best at a dull red visible in daylight. Stands up at temperatures at which high speed steel burns. Cooperite requires no heat treatment. The zirconium with its extremely high melting point is apparently cause of heat resistance. Material is cast and ground and cannot be forged. Photographs show nature of work. *Raw Material*, 4-22, 2000 w. APS.

Automatic Seam-Welding in Making of Tubes. Automatic welding as a commercial process is set down as a combination of temperature, exterior pneumatic force, speed and mechanical pressure. Variation in degree in any one of these is fatal to the success of the operation, and thus, to the plant using it. Author takes up each of these, then all of the available machines, describing the methods of preventing wind, of counteracting strains, of avoiding wave formations. He tells also how to grind the weld, how to conduct the swaging operation successfully and goes into other details. J. L. ANDERSON, *Can. Machinery*, 5-4-22, 3800 w. MAH.

Arc Welding in Machinery Construction. Large variety of defective or accidentally damaged shop machinery is effectively repaired by arc welding. Examples (with photographs) are given of a large flywheel, a large lathe bed, shafts machined undersize, etc. Coasting vessel (500 tons dead-weight) was built all arc welded without rivets. Small mill building (40x60 feet) was erected by welding process. Ammonia tanks can be successfully arc welded. Description of modern arc-welding generator set. A. M. CANDY, *Engineering World*, 4-22, 2500 w. APS.

Duralumin: Commercial Possibilities. Review of properties and heat treatment. Use in gears, pinions, connecting rods, etc. Five times as costly as cold-rolled steel, but one-third the quantity is used, thus decreasing the price differential. Saving in labor, etc., so that duralumin structures in certain cases are cheaper than steel. Detailed discussion of thicknesses, forms, etc. Predicts use more universal than steel for structural purposes, in automotive industry, railway and street cars, bridges, boats and buses. Table of physical properties. W. B. SROUT, *Brass World*, 4-22, 1200 w. APS.

Lead Burning Today. Lead burning (really lead welding) has developed through increase in storage battery industry and great expansion of chemical industries. Describes joints; butting and lapping. Formerly used hydrogen and compressed air, today use illuminating or natural gas and compressed oxygen. Acetylene and hydrogen also used. H. B. SHONTZ, *Motor Rec.*, 4-22, 1500 w. APS.

A B C of Sheet Metal Working Machinery. Operations and description of hand equipment used in manufacturing tin cans in limited quantities. Output of 100 to 1000 cans per ten-hour day, 2 to 6½ inches diameter, 2 to 9 inches high. L. BROEMEL, *Sheet Metal Worker*, 4-28-22, 9 figs., 1500 w. APS.

Standard Methods of Testing Materials. Report on analysis of aluminum sulfate, basicity or acidity of alum, lime for causticizing, crown filler and specifications from American Writing Paper Co. for crown filler. F. BECKER, *Paper Trade J.*, 4-13-22, 2500 w. CJW.

Paper Manufacturers Seek New Outlet

ACCORDING to the bulletin of the American Paper and Pulp Association, new uses for paper must be found to take up the present large surplus of machine capacity. Before 1914 the industry was operating at about 80% of capacity, but during the war the full capacity was absorbed and during the last three years 120 machines, with an annual capacity of 1,675,000 tons each, have been added, increasing the total capacity 23%.

Although the improved conditions in the industry which were beginning to be evident in April have continued into

May, with further increases in orders and generally better prospects for business, it is estimated that under normal conditions the 1922 production would be 6,800,000 tons of 78½% of capacity. It will take until 1925 for the industry to get back to the production of 1914, if only the normal increased consumption of 200,000 tons per year is maintained. It will take until 1928 to get the industry up to 90% of capacity. Since a paper machine can be operated successfully only when running practically to capacity, the finding of new outlets for the product of the machines appears to be the only solution.

Drying of Paper. Considers properties of paper under heat, drying conditions, heat supply and removal of water vapor. Drying conditions must be arranged to satisfy characteristics of paper under heat so that most rapid satisfactory drying rate is maintained. In drying paper 25 per cent of total water removed is by suction, 45 by first press, 3 by second press, 26 by drier, with 1 per cent remaining in felt. More cannot be removed by press rolls because caliper of sheet is reduced too much. In drying first requisite is dry steam entering dryers, which should be as high pressure as possible considering quality factor. Circulation is necessary to efficient operation, since it governs water and gas films inside dryer. Air systems for removal of water vapor must have capacity to carry away water vapor, be able to produce humidity difference between water vapor on sheet and humidity of air carrying water and must have velocity past sheet. Types discussed and drying curves given. M. B. LITTLEFIELD, *Paper Trade J.*, 4-13-22, 3000 w. CJW.

Chemistry of Sulfite Process. Method of procedure for study of chemistry of sulfite process has been tested and found to be workable. Methods of analysis have been tested and applied to preliminary study. Application of Sander reaction and reversible sulfur dioxide determination, to control of sulfite cook have been tested and found of value. Information as to character of pulp produced at different stages in sulfite cook has been secured. Importance of content of free sulfurous acid at end of cook has been pointed out. R. N. MILLER and W. H. SWANSON, *Paper Trade J.*, 4-13-22, 4000 w. CJW.

Bleach Liquor. Discussion of adaptation of liquid chlorine to bleaching of those fibers which do not respond to acid bleach or where, because of large amount of chlorine necessary, it would be impractical to carry it in solution in water. Work narrowed to lime base because of cheapness. Calcium hypochlorite thus produced, which is same chemical composition as solutions made from dry bleach, but possesses different physical properties. Economies effected are: saving chlorine usually washed to sewer with sludge, use of material that will not decompose during transportation and

storage, producing nearly neutral bleach that is extremely active when in contact with pulp. Plant described. S. W. JACOBS and H. P. WELLS, *Paper Ind.*, 4-22, *Paper Trade J.*, 4-20-22, 3000 w. CJW.

Cotton Linter Pulp. General description of process of manufacture of cotton linter pulp. Linters will give rag content with direct proportion to amount used. Most desirable for permanent records, since they contain 98-99 per cent alpha-cellulose. Linters will fold with best quality of new rag, but pop test falls somewhat short of higher grade new rags, being about equivalent of fancy shirts. Gives somewhat more bulk to paper for same unit of weight. Cheaper than old rags. S. E. SEAMAN, *Paper Trade J.*, 4-13-22, *Paper Mill*, 4-15-22, 2000 w. CJW.

Efficiency of Grinders. Economical advantages to be derived from operation of automatic magazine type grinder when compared with pocket type grinder are: maximum production per hp. consumed, lower labor cost per ton of pulp, partial steaming of wood at no additional expense, low cost of maintenance and repairs, use of 4 ft. wood, eliminating at least one sawing operation, cleanliness of grinder room, elimination of considerable labor difficulties, use of wood up to 30-in. diameter and saving of floor area and foundation work. J. J. CASE, *Paper Trade J.*, 4-13-22, *Paper Mill*, 4-15-22, *Paper Industry*, 422, 1800 w. CJW.

Power Plant of Paper Industry. Each pound of paper necessitates from 4 to 6.85 lbs. of steam. Mechanical energy to produce paper from logs as delivered amounts to 0.0437 HP. per lb. of paper. Heat balance can be obtained and further maintained by application of properly designed equipment. Modern practice tends toward use of higher steam temperatures and pressures. Discussion of best equipment. *Paper Mill*, 4-15-22, 2000 w. CJW.

Beater-Room Hazards. Modern beating engine nearly fool-proof. Minor dangers must be guarded against always. Concrete floors are desirable to avoid slipping on wet floors. Elevated tanks of all varieties must be guarded by railings and platforms with toe boards. Valves should not be weighed down when next beater is being dumped. Pulley-driven lines must be guarded and motor-driven lines must be watched because beater room is wonderful conductor. C. WALKER, *Pulp Paper Mag.*, 4-20-22, 500 w. CJW.

Sulfur and Sulfur Burners. Chemistry of sulfur discussed. Oldest type of burner is flat type. Rotary and vertical more efficient. Description of construction and operation. Plant operation facilitated by liberal supply of sulfur, stored in number of smaller bins rather than one large one to decrease fire risk. Accurate inventory of sulfur should be maintained. H. E. WESTON, *Paper Industry*, 4-22, 1600 w. CJW.

Removal of Odors from Digester Blow in Sulphate Mills. By using a barometric condenser instead of the usual tube or surface condenser, the steam is better condensed and the odoriferous gases are more thoroughly absorbed. In addition the air which is always entrained with a barometric condenser spray oxidizes the ill-smelling sulphides and completely destroys the odor of the exit gases. GUSTAF F. ENDERLEIN, *Paper Mill*, 4-29-22, detail sketch, 1000 w. APS.

Fibre Cans. Fibre can economy well balanced and cumulative. Original purchase price far less than cost of metal, saving in time of labeling, and weighing less, requires less heavy packing cases and reduce freight charges. Flexible, they take shock like pneumatic tire and hold original shape. Make favorable impression on consumer. Article shows styles, sizes, shapes and types of construction. *Fibre Container*, 5-22, 1000 w. CJW.

Manganese Steel in Jordans and Beaters. The toughened heat-treated manganese steel beater roll and jordan fillings are practically indestructible. The performance of these parts makes possible better design of machinery. J. H. HOCK, *Paper Mill*, 5-6-22, 750 w. APS.

House Organ Headquarters

**WILL HELP YOU ESTABLISH THAT EMPLOYEE PUBLICATION
OR SALES ORGAN YOU ARE THINKING ABOUT**

Ours is a Planning, Writing, Editing, Printing and Art Service Distinctively Qualified for House Organ Work.

Tell us how much you want to spend and we'll give you a definite idea of the publication that amount will buy. And we will furnish a Magazine or Paper that will fit into your needs.

We Specialize in Industrial and Institutional Publicity Designed to Reach the Employee

Our Service Eliminates Costly Experimentation

Have You Seen the Blue Pencil?

Send 30 cents in postage for a sample copy

The only Trade Paper devoted exclusively to the subject of Employee Publications, House Organs, etc. It deals in a Practical way with every phase of publication work.

Planning, editing, gathering news, articles and information, how to buy and use art and engravings, etc. It contains 80 and sometimes 96 pages of information.

HOUSE ORGAN HEADQUARTERS, 187 Montague Street, Brooklyn, N. Y.

The Saving Grace

as applied to magazines, means the retention of all issues which may be worth something later on. We submit that *each* copy of the *Industrial Digest* is worth saving because of the more than five hundred digests of important articles which it contains. The Annual Cumulative Index which will be sent without charge to all subscribers will make this valuable data instantly available, *provided* the copies are filed for reference.

And for this purpose we are prepared to furnish neat, strong, handsome binders, done in black cloth with gold lettering, and capable of holding a year's copies, at the moderate rate of two dollars each.

Order now and keep your copies in good condition.

TEXTILES

Textile Raw Materials Advancing

WITHIN the last few weeks the unexpected rise in the price of textile raw materials has taken place. Cotton, silk, wool, jute and flax have all shown a tendency to advance. According to *Dun's Review* the rise in the price of wool is world-wide, but has become pronounced in this country because of the probable enactment of a tariff imposing a high duty on raw material, to take the place of the emergency tariff now in force. In raw silk and jute crop shortages have been reported. In cotton, the rise in price has been influenced by a number of factors. Chief among these has been Washington's estimates of a larger world's consumption, statistics of the Department of Commerce indicating that the total for the season ending July 31 would about equal that of the pre-

war period. Reports of unfavorable weather in Texas, active Southern buying, strong Liverpool cables, an increasing demand for domestic manufactures, the improved political outlook in Europe, and an optimistic sentiment in local speculative circles, due to the strength of the securities market also contributed to the rise in price.

In every instance, however, the goods markets are reported to have been affected adversely by the low purchasing power of the country, and the increasing competition among retail and wholesale stores. Merchants are doubtful as to whether there will be much change in purchasing conditions, and it is believed that for some time to come the lack of money to buy freely will stiffen public resistance against rising prices.

Organic Acids in Treatment of Textile Fabrics. Treatment with acetic acid results in little deterioration. Sulfur dyes not affected; uneven dyeings with basic colors may be avoided. Oxalic acid has little tendering effect, and is useful in many discharge processes and in fixing fabrics mordanted with tannic acid (as potassium antimony oxalate), though tartaric acid may be employed more extensively. Citric acid is useful in discharging iron, aluminum and chrome mordants and is therefore useful in printing madder styles. Formic and lactic acids are also increasing in favor. Lactic acid can be used in chroming of wool and luster and soft handle are not diminished in this treatment. Lactates may be used in place of tartar emetic. Also used in discharge processes and in aniline black printing. A. J. HALL, *Am. Dyestuff Reporter*, 4-24-22, 1500 w. CJW.

Lubrication of Wool. Correct lubrication of wool fibre, though of greatest importance, is usually neglected except in large mills. Oil should be added after wool is dry and clean; before carding and spinning process begun. Cheap oil requires more scouring to remove in finishing process of cloth. Potash soaps less hard on wool fibre, but more expensive than soda soaps, which are generally used. Impossible to use soda and hot water on dyed goods. Oils must have low flash point and not turn

rancid quickly. Mineral oil is cheapest, used most frequently, often with dire results. Vegetable oils are much better. Animal or lard oils are popular, as, being animal, they are akin to natural grease of sheep, making the best wool lubricant. B. X. C. BAILY, *Canadian Textile Jour.*, 4-25-22, 800 w. MBB.

Gummed Cloth Sealing and Binding Tapes. Well-known puncture test has proved utterly inadequate to determine strength of cloth tape for binding purposes. Many different types of apparatus for determining tensile strength, but the varying results very disturbing. In designating medium grade, following specifications are recommended as standard; cloth tape to have not less than sixty filling threads to the inch of size not less than No. 38; for heavy grade, not less than forty-eight filling threads to the inch of a size not less than No. 20. C. H. CROWELL, *Canadian Textile Jour.*, 4-25-22, 600 w. MBB.

Acetyl Silk Dyeing. Acetyl silk, new ester—silk now entering market. Gives methods of dyeing it. J. F. BRIGGS, *Textile Colorist*, 4-22, 2500 w. To be continued. WRR.

Jute Bleaching and Dyeing. Give properties of jute, preparation, methods of bleaching, dyeing, and how to use various dyes, printing. E. DUHEM, *Textile Colorist*, 4-22, 5000 w. WRR.

Causes of Shadiness and Cloudedness. Caused because goods are poorly prepared, uneven steam pressure, steam not allowed to pass through goods evenly, uneven roller pressure on crabbing machine, varying temperature of water, goods rolled up wet to set filled with dirty water, and in dye kettle, goods taking up dye too fast caused by admission of steam too rapidly. Use of too much acid is also factor. Many so-called shady goods due to uneven shearing from shears and uneven pressure in dry finishing. Not altogether dye-house problem, but usually charged to dye-house. F. E. JOHNSON, *Am. Dyestuff Reporter*, 750 w. CJW.

Cost Finding in Knitting Mills. Necessary in order to meet competitors' prices. Conservation of resources; accurate planning; organization; organization analysis. STEPHEN R. GORDON, *Textile World*, 4-15-22, 4500 w. To be continued. WRR.

Woolen and Worsted Cloth Finishing. Covers use of horizontal blowing machines; blowing and its effect on fabrics; defects produced by blowing; boiling and its defects; machinery used for boiling. TEXTUS, *Textile American*, 4-22, 7000 w. To be continued. WRR.

Mixed Cotton and Silk Piece Goods Dyeing. This number upon dyeing and printing aniline black. Four different aniline black effects. Defects and methods of using. RAFFAËLE SANSONE, *Textile Colorist*, 4-22, 1200 w. To be continued. WRR.

Removing Yarn Kinks in Twisting. Illustrated description of simple attachment for twister frames that can be made in any mill carpenter shop. RADIAL, *Textile World*, 4-8-22, 800 w. WRR.

A Graphic Analysis of the Best Cotton Regain Conditions.—(Prepared by Park-Cramer Co., and Published in *Cotton Mill News*).

Nothing But Wages

Far-sighted employers are realizing that times have changed, and that the minds of men have changed with them. The tremendous appeal of the great war inspired the workers in plant, mill and factory with a desire to associate their efforts with an *ideal*. The employer who pays a fair wage only can expect to fail in securing his proper return in a harmonious, productive organization. Humankind which for a century was repressed on every hand has had its taste of the joy of self-expression, and will not extend itself if fed on the husks of nothing but wages. This has a direct bearing on you and your employees.

1,000,000 Carloads of Gravel for Roads

THE remarkable increase in road construction in this country, says *Steam Shovel and Dredge Magazine*, is evidenced by the fact that during the past year more than 1,000,000 men found employment at building and repairing the Nation's thoroughfares. The different classes of roads completed totaled 24,000 miles—almost equal to the earth's circumference.

The 1922 program of the Federal Bureau of Public Roads calls for the construction of approximately 10,000 miles of improved highways, sixteen States having already submitted plans for the building of this mileage. The Government survey shows that there are more than 300,000 miles of improved roadways in the country, and about 2,500,000 miles of roads

that might be greatly benefited by even a small amount of work upon them.

The beneficial effect of increased activity in roadway construction upon allied industries is indicated by the fact that 50,000,000 tons of gravel and stone will be required for the Federal highways completed and under construction at the close of 1921. This means 1,000,000 carloads and is equal to the total annual production of all commercial sand and gravel plants in twenty-nine States in the eastern half of our country. Federal roads under construction or completed last year called for 17,000,000 bbls. of cement, or about one-sixth of the largest annual production on record.

Economics of Highway Transport.

Topical outline is as follows: Field of highway transport, 3 sections; Highway and motor vehicle, 5 sections; Legal phase, 3 sections; Principles of successful operation, 7 sections; Selling transportation, 5 sections. *Automotive Industries*, 3-16-22, 800 w. WRR.

Asphalt Filler for Brick and Block Pavements.

Need for stable material indicated by experience. Asphalt will not crack in cold weather, or become soft and flow in hot weather. Methods of applying filler given. CHAS. E. MURPHY, *Highway Engineer and Contractor*, 5-22, 700 w. CS.

Experience Gained from Tests of Railcars.

After a general summary of the usual railway tests of new cars and new power units, the author describes recent tests of a new Gramm three-ton railcar chassis. The results are compared with those of a mountain type passenger locomotive as used on the Norfolk & Western. In proportion, the capacity of the railcar being very much smaller, the tests were favorable. DONALD A. HAMPSON, *Automotive Industries*, 4-6-22, 3100 w. MAH.

Double Truck Lightweight Car for Bangor.

Description of new Wason-built one-man cars just put into operation by the Bangor Railway & Electric Co. These cars weigh about 28,000 lbs. and seat 52 passengers, as compared with last previous installation of cars, which weighed 46,000 lbs. each and seated but 44 passengers. They have proved efficient in use, coming through the heavy snowstorms of February without any delays or difficulties whatever. Article gives complete details of design, construction and equipment of these more economical cars. HORACE B. BALDWIN, *Electric Traction*, 4-22, 1100 w. MAH.

DAVIS Valve Specialties *serve*. Their basic design has remained unchanged for many years while new principles have appeared, have failed, and have been discarded. Working in a straight line always, avoiding the pitfalls and by-ways, Davis has added refinement to refinement until today veteran engineers will tell you that for dependability and staying power you cannot rival—

Davis Regulators that give accurate steam pressure reduction and maintain the reduced pressure steady

regardless of fluctuations in the initial pressure. They have no springs or diaphragms to cause trouble and shorten their life. Regulators are made in types and sizes for all pressures and conditions.

Davis Back Pressure Valves never stick or bind; made in all sizes for maintaining a positive back pressure for heating, drying, cooking, or other purposes.

Davis Stop and Check Valves have their dash pot outside of the valve body away from the action of the steam where it cannot cause trouble. Ask the G.M. Davis Regulator Co., 409 Milwaukee Avenue, Chicago, for details of these and the other valve specialties listed opposite.

ANDREW JAY FRAME
CHAIRMAN OF THE BOARD,
THE WAUKESHA NATIONAL BANK, WAUKESHA, WIS.

If stability in banking is to maintain, and if general stability is to become the rule in all material progress, then large enterprises especially desiring credit should furnish to creditors or banks, say annually, at least, a certified audit made by some competent, fearless and honest expert in the audit line.

This statement seems to me a fundamental to ensure solid human progress, because it gives the best known enlightenment, next to judgment of men, as to whether solvency reigns or an over-expanded condition of the debtor exists.

*Published in the interest
of better business*
By ERNST & ERNST

Andrew Jay Frame

Weathervane

(From page 1051)

pressure to reduce wages, while the falling retail prices act to weaken the resistance of the wage earners to moderate reductions. This last effect is, however, partly offset by the continued high prices of rents, light and fuel. The coming summer should, therefore, see the practical completion for the present of the downward readjustment of wages."

Dun's Review makes the prediction that "With the stronger underlying conditions, the current business recovery reflects more positive characteristics of

permanency. Progress is still impeded by labor troubles in certain industries, but response to vonstructive factors is more clearly evident in the improved sentiment and revival of buying and the reversal of the price movement has become more decisive. Declines in various markets, continuing for many months have been succeeded by an advancing tendency and demand in different instances is being stimulated by the prospect of higher quotations to follow. Except in retail channels, where price concessions have not infrequently been necessary to maintain distribution, most sellers are now more favorably situated."

Prices Going Up?

(From page 1063)

appear to regard rising prices as essential to prosperity. Those who hold that the chief aim of the business man is to 'buy cheap and sell dear' are naturally desirous of maintaining a bull market at all times, though it is obvious that prices cannot rise perpetually. There are times when prices are too low and also times when they are too high. Rising prices produce a happy psychological effect on the business community, and sometimes a tonic of this sort is badly needed.

"There are some occasions when an advance in prices tends to stimulate production and thereby increase employment and enhance the buying power of consumers. Such a price movement is constructive. If business is forging ahead at full speed, however, with practically all industrial plants booked up to their full capacity, a further advance in prices will neither stimulate production nor increase employment. Instead of enhancing the purchasing power of consumers it tends to cripple it, and there soon develops the vicious circle of rising prices, followed by higher wages, which necessitate still higher prices and in turn still higher wages. Such a movement is never constructive; it produces only an inflationist bubble which eventually must burst. The price advances of 1919-1920 were of this character. On the other hand, the recent firmness of prices in some of the basic industries has been accompanied by increased production and more employment. So long as the advance has this effect it is beneficial. The time to take such action is during the period of adjustment. When inflation once gains headway the remedies will be too late."

The Fortnight

(From page 1053)

and with him are said to be J. H. Sanford, president of the Carnegie company and William N. Henderson of the Henderson Coal Company. The new company, the name of which has not yet been chosen is to have an annual capacity of 6,000,000 to 8,000,000 tons.

Congress Is Stagnant

CONGRESS is still fumbling around with the tariff bill. All efforts to hasten its passage have apparently failed. The bonus bill, which was reported out of the Finance Committee, will probably not pass until the tariff measure has been put through. The bill will not be effective until January 1, 1923, in any event, so there is no advantage in passing it except for the political effect on the fall elections. All indications now point to a speedy passage of the ship subsidy bill.

Coincident with the rise in prices on practically all commodities there is a steady continuance of wage cuts. This means that the purchasing power of practically all workers is steadily being lowered—with the exception of the farmers. Our farm population is about 35 per cent of the total and consequently when the Department of Agriculture reports that the farmer's purchasing power has increased almost 25 per cent it is a very healthy indication of returning prosperity.

A Master Key to the News of Business

OUT of all the flood of information that pours in on you through newspapers, trade papers, magazines and other sources, how are you to sort out the pertinent facts that bear on your business? Wouldn't a master key to the news of business be worth (literally) its weight in gold to you?

THE INDUSTRIAL DIGEST is precisely such a service. Out of all the news of the daily press, the trade and business press and all other sources, it selects, verifies, evaluates and arranges the business facts of importance and sets them forth digested and indexed—and interestingly presented.

THE INDUSTRIAL DIGEST presents the business fortnight in perspective. It offers the major executive in every field of business the opportunity to keep himself acquainted, with a minimum of attention, with important events in his own industry and in other fields of business as they bear on his own.

IT costs tens of thousands of dollars a year to prepare THE INDUSTRIAL DIGEST. But the subscription price to each executive is only five dollars a year.

This coupon will bring the service to you once every two weeks for one year.

THE INDUSTRIAL DIGEST,
25 West 45th St.,
New York City.

Please send your fortnightly survey of American industry and commerce to me for one year. I enclose five dollars, check or money order.

INDUSTRIAL CALENDAR

Secretaries of Associations are invited to send us the dates of their conventions as early as possible so that their conventions may be properly listed below. When especially requested by Association Secretaries, we will send dates and other available notices concerning meetings of other associations.

- June 11-15. *Associated Advertising Clubs of the World*, Milwaukee, Wis. (P. S. Florea, Secretary, 110 West 40th St., New York.)
 June 12-15. *National Association of Retail Credit Men*, Cleveland, O. (W. Reis, Chairman, 15 West 37th Street, New York City.)
 June 12-16. *National Fertilizer Association*, White Sulphur Springs, W. Va. (John D. Toll, Secretary, 1010 Arch St., Philadelphia.)
 June 12-16. *American Pharmaceutical Mfrs. Assn.*, Bedford Springs, Pa. (R. R. Patch, Secretary, care of E. L. Patch & Co., Boston.)
 June 13. *Music Publishers Association of U. S.*, New York City. (E. T. Paull, Secretary, 243 West 42d St., New York City.)
 June 13-15. *Illinois and Wisconsin Retail Coal Dealers Association*, Hotel Highland, Delavan Lake, Delavan, Wis.
 June 13-16. *Linen Supply Association of America*, Chicago, Ill. (F. H. Hartless, Secretary, 646 North Parkside Ave., Chicago, Ill.)
 June 14-16. *International Circulation Managers Association*, Indianapolis, Ind. (C. Eyster, Secretary, "Evening Star," Peoria, Ill.)
 June 14-21. *American Railway Association, Mechanical Division*, Atlantic City, N. J. (V. R. Hawthorne, Secretary, 431 South Dearborn St., Chicago, Ill.)
 June 18. *American Train Dispatchers' Association*, Chicago, Ill. (C. L. Darling, Secretary, 1310 Mallers Bldg., Chicago, Ill.)
 June 19-21. *American Railway Association, Purchases and Stores Division*, Atlantic City, N. J. (J. P. Murphy, New York Central Ry., Collinswood, Ohio.)
 June 19-21. *Stoker Mfrs. Assn.*, Groton Pt., Conn. (J. G. Worker, Secretary, Eau Claire, Wis.)
 June 19-23. *National Retail Hardware Association*, Hotel Sherman, Chicago, Ill. (Herbert P. Sheets, Secretary, Argos, Ind.)
 June 19-24. *National Association of Building Owners and Managers*, Bedford Springs, Pa. (H. G. Loomis, Secretary, Omaha National Bank Bldg., Omaha, Neb.)
 June 20-23. *Society for the Promotion of Engineering Education*, University of Pittsburgh; Annual Convention, University of Illinois.
 June 20-23. *National District Heating Assn.*, Cedar Point, Ohio. (D. L. Gaskill, Secretary, Greenville, Ohio.)
 June 20-23. *Lions International Convention*, Hot Springs, Ark. (Melvin Jones, Secretary, McCormick Bldg., Chicago, Ill.)
 June 20-24. *Society of Automotive Engineers*, White Sulphur Springs, W. Va. (C. F. Scott, 29 W. 39th St., New York City.)
 June 21-22. *American Society of Civil Engineers*, Annual Convention, Portsmouth, N. H.
 June 22-23. *National Hardwood Lumber Association*, Congress Hotel, Chicago.
 June 26-27. *National Ornamental Glass Mfrs. Assn.*, Cincinnati, O. (C. C. Jacoby, Secretary, 2700 St. Vincent Ave., St. Louis, Mo.)
 June 26-30. *American Institute of Electrical Engineers*, Niagara Falls, Ont. (29 W. 39th St., New York City.)
 June 26-July 1. *American Society for Testing Materials*, Chalfonte-Haddon Hall Hotel, Atlantic City, N. J. (C. L. Warwick, Secretary, 1315 Spruce St., Philadelphia.)
 June 28-29. *American Association of General Baggage Agents*, Minneapolis, Minn. (E. L. Duncan, 332 South Michigan Ave., Chicago, Ill.)
 July 9-12. *International Association, Display Men*, Chicago, Ill. (L. A. Rogers, Secretary, John D. Mabley Co., Detroit, Mich.)
 July 10-15. *Export & Import Exposition*, Baltimore, Md. (A. E. MacKinnon, 405 Lexington Ave., New York.)
 July 16. *American Institute of Banking*, Portland, Ore. (R. W. Hill, Secretary, 5 Nassau St., New York.)
 July 25-28. *National Retail Tea & Coffee Merchants Assn.*, Hotel Statler, Detroit, Mich. (R. M. Heizer, Secretary, 1201 Cornell Ave., Indianapolis, Ind.)
 Aug. 23-25. *American Association of Railroad Superintendents*, Kansas City, Mo. (J. Rothschild, 400 Union Station, St. Louis, Mo.)
 Aug. 28-Sept. 2. *National Safety Council*, Detroit, Mich. (S. J. Williams, Sec., 168 N. Michigan Ave., Chicago, Ill.)
 Sept. 11-15. *Association of Iron and Steel Electrical Engineers*, Cleveland. (J. F. Kelly, Secretary, Empire Bldg., Pittsburgh.)

Foreign Events

- June to November. *French Colonial Products*, Marseilles, France.
 June 15-24. *International Exhibition of Foundry Equipment and Materials*, Birmingham, England.
 June 15-Sept. 15. *Annual Exhibition of Ceramics and Glassware*, Dresden, Germany.
 July. *Second Near East Sample Fair*. New exposition buildings being erected along the Danube.
 July 1-24. *Aircraft Exhibition*, London, England.
 July 9. *Universal Exhibition*, Buenos Aires, Argentina.
 July 24-29. *International Tobacco Trade Exhibition and Conference*, London, England.
 Aug. *Second Sample Fair*, Lublyana (Leibach), Yugoslavia.
 Aug. 12-20. *Third Annual Sample Fair*, Liberee (Reichenberg), Czechoslovakia.
 Aug. 27-Sept. 2. *Autumn Fair*, Leipzig, Germany.

SEDGWICK

Going a Step Further

SEDGWICK goes a step beyond supplying you with reliable equipment, especially fitted to fulfil your particular requirements.

Over a quarter century's experience has shown us that lifting and lowering equipment, to operate properly, must be *properly installed*.

We have in our files the records of thousands of installations made under almost every conceivable condition. This mass of accumulated data enables us to direct the installation of your Sedgwick equipment according to principles and methods that have proved best over many years of actual use.

So when you buy Sedgwick Hand Power Elevators, Dumbwaiters, or Gravity Lifts, your satisfaction is assured, not alone by superiority of manufacture and design, but also by Sedgwick supervision and direction which continues until your outfit is in perfect condition for regular use.

For lifting
and lowering—
SEDGWICK

In the home, as well as in industry, Sedgwick outfits have been in wide daily use for more than a quarter century. Sedgwick Hand Power Dumbwaiters and Invalid Elevators are of greatest convenience and perfect reliability.

Write us and ask how Sedgwick Hand Power outfits can help solve your lifting and lowering problems.

New England's Cotton Mills
Are Fighting for Existence

Why bankers give you this added protection

Bankers, as a whole, are working to one final goal—absolute safety for depositors' funds.

Each year they spend thousands of dollars for burglar-proof vaults, burglar alarms, fire alarms and innumerable contrivances to thwart the crook. Yet, all this money for protective measures would be wasted if the check-raising crook operated freely. Your funds in your bank are subject to withdrawal to the amount shown above your signature on any check you write. If someone increases this figure to more than you intended it to be, you lose—UNLESS you are protected by insurance against such depredation.

Super-Safety Insured checks provide the final link in the chain of safety that bankers are welding around your funds on deposit with them. They close the last loophole open to the crook.

Every bank using Super-Safety Insured checks is insured for \$1,000.00 against loss through fraudulent alteration, and each of its depositors is insured for like amount against similar loss.

This insurance is your positive protection against any loss through check raising. It beats all the ingenuity ever devised for such protection. You can write Super-Safety Insured checks by pen or typewriter, and be positively protected.

Ask your banker for these checks, or write us for the name of one in your locality who will gladly accommodate you.

*\$1,000.00 of check insurance
against fraudulent alterations,
issued without charge,
covers each user against loss.*

It's Time to "Pick Up the Pilot"

*A problem for the President, General Manager,
Director, Secretary or Treasurer.*

Each business today is headed for a new port:—

"The commonly accepted but traditional and antiquated methods of cost accounting, prevalent in so many plants, are falling down under the pressure of modern manufacturing methods. These accounting methods, disguising as they do the real costs, and presenting instead fictitious costs whose real values are thoroughly concealed, have no place in the modern American intensive production manufacturing plant. *What our managers need is not a cost system whose primary purpose is to lend itself, through the accounting department, to a financial audit, but a cost system which is primarily designed to reveal true costs in time to control them and to prevent them from becoming excessive.*"

THE EDITORS,
Industrial Management.

Methods of production planning, of accounting, and most emphatically of cost determination, perhaps efficient in other days, have now become an inadequate *collection of habits—rut-running habits.*

Can your decisions and policies in meeting present conditions, then, be other than fettered by such habits—these "ghosts of yesterday"?

The solution lies not in revolution, but in evolution; through a fresh point of view and the application of sound economic principles.

Your accounting, costs, production planning and sales, under our consulting supervision (based upon an experience of 30 years) will reveal new profit opportunities. We can arrange a service to fit your particular needs—and pocketbook. "It's time to pick up the pilot." At least, let's talk it over.

Our bulletin, "Straight Talk," an exceedingly informal two-minute chat on management problems, will assist executives who have ambitions to satisfy. Your request on your letterhead will bring a complimentary copy.

What Is the Answer?

"Where can I effect the greatest saving in my manufacturing costs?" is a question we are often asked. The specific conditions existing in the plant in question determine the answer, of course, but in a surprisingly large number of cases the answer is found by our staff of engineers and expert accountants to be—"By utilizing the full capacity of your equipment every working hour."

Manufacturing plants seeking to increase their output are sometimes found to be underequipped—but more often they are *underoperated*.

If your plant is underoperated—if machines and equipment (and even men) are not being utilized to their greatest advantage *every* working hour—that is **your** business. If you are interested in finding out just *where* the waste occurs and in learning exactly *how* to eliminate your trouble that is **our** business.

The Business Weathervane

A Summary of Expert Opinion

In the opinion of the **Brookmire Economic Service**, "the usual summer let-up in business is beginning to appear and should be expected, but this year is quite the opposite from last year, as we were then in widespread depression from which we did not begin to emerge until late summer. Now we have had ten months start on the road to prosperity with the outlook measurably brighter for fall trade than a year ago. The next two months will be in the nature of a breathing space during which further strength will be

gathered for a greater effort and more decided advance."

The **United Business Service** points out that "the continual ebbing of the tide of failures is significant for the determination of credit extensions, and for some time to come a diminishing degree of hazard will be experienced by credit grantors. The total number of failures as well as total liabilities for the month of May were the smallest since last October.

"The present period of the business cycle, with a gradually declining rate of business mortality, is a far less hazardous time to extend credit than during an inflationary period when the natural inclination is to do otherwise. We believe, therefore, that these facts justify further emphasis at this time of a policy of greater leniency in credit extensions."

According to the **Graphic Investment Service**, "Mail-order sales are now improving. They continued to fall off throughout almost the whole of 1921, and it is only since February that a marked recovery has set in. Since they reflect with considerable accuracy the buying power of the farmer, this belated improvement is very welcome. Com-

modity prices in general have risen 12% during the past year. That would have been esteemed a considerable advance in pre-war times, and it has a decided effect in encouraging merchants and business men to take on their ordinary stocks of goods."

B. C. Forbes believes that "Nothing—not even a crop failure—would more surely decree the killing of the healthy recovery now under way than shortsighted boosting of prices. The public is beginning to spend money with almost normal freedom, except that prices are still closely scrutinized and a good deal of "shopping" is indulged in, especially by women, before purchases are actually made. As employment increases, and as our enormous agricultural population begins to receive money for the 1922 crops, the total purchasing power of consumers will increase. Just how much purchasing will increase will depend more than anything else upon how prices strike potential buyers. The public has not forgotten how prices were inflated during the war and how effectively they stopped the whole business by simply refusing to buy. It would be in the last degree unwise for the business world to do anything calculated to instigate any recurrence of such resentment and such a 'strike.'"

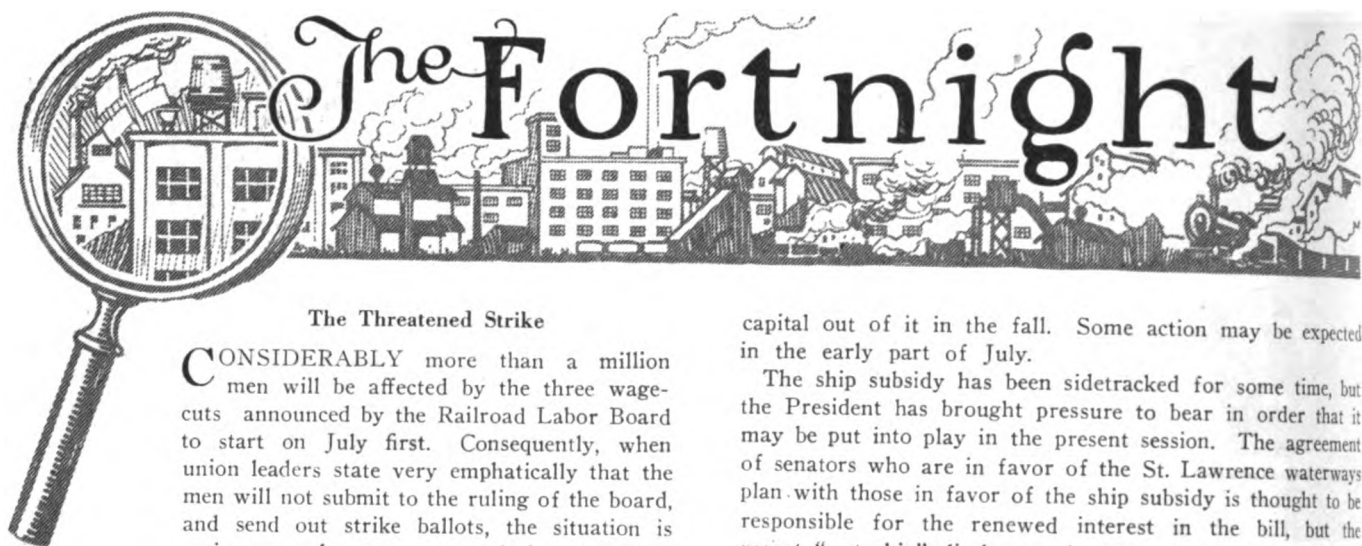

(Forbes Magazine)

Wife "Don't forget, I'm here, dearie."

situation and continued strikes in some industries, the business recovery is being extended. Abatement of demand in certain quarters has followed recent large purchasing, but indicates no diminution of confidence, and the large excess of advances in Dun's list of wholesale quotations demonstrates that the upward price trend is gathering momentum."

Dun's Review points out that "Despite new elements of uncertainty in the labor

The Threatened Strike

CONSIDERABLY more than a million men will be affected by the three wage-cuts announced by the Railroad Labor Board to start on July first. Consequently, when union leaders state very emphatically that the men will not submit to the ruling of the board, and send out strike ballots, the situation is serious merely on account of the magnitude of the affair. The ballots have been mailed, and the vote is being taken with every indication pointing to approval of a nation-wide strike tying up practically all rail transportation. Unless level-headed leaders can hold the more radical element in check, the country may be treated to another tieup. Few responsible men on either side of the controversy seem to feel that the matter will come to a head, and experienced observers agree that if the strike is called it will be more in the nature of a demonstration to save the union's face than a serious attempt at avoiding the reduction. The demonstration may take the shape of a strategic withdrawal of enough "key" men to cripple the roads. The rail unions are endeavoring to make the most of the matter, however, and there has been much talk of tying up the proposed rail strike with the coal miners who are already out, linking some 680,000 bituminous coal strikers with the railroad groups in their effort to hold on to gains made during the war. It does not seem likely that so heavy a blow at union labor will find the unions unprepared to take some sort of action, but, on the other hand, labor has learned a lesson from the last year's crop of strike failures, and will probably heed the warning of its conservative leaders before plunging into a long-drawn-out battle. The Labor Board is preparing a statement answering the union's threat to strike.

Congress Still Procrastinates

THEN too, a strike would be the signal for action by the Administration, especially with the fall elections just around the corner. The fact that Congressmen are fretting in Washington, and are anxious to get home and repair their political fences is sure to have its influence on other matters of importance before Congress. It has been thought by many editors that the tariff would not go through at this session, but others point out that the Democrats are planning to let the bill pass for the express purpose of making political

capital out of it in the fall. Some action may be expected in the early part of July.

The ship subsidy has been sidetracked for some time, but the President has brought pressure to bear in order that it may be put into play in the present session. The agreement of senators who are in favor of the St. Lawrence waterways plan with those in favor of the ship subsidy is thought to be responsible for the renewed interest in the bill, but the recent "wet ship" disclosures have not improved its chances any. The bonus measure is still dormant. It is not certain that the bonus will be passed at the present session, since many Congressmen believe that they can put the blame for failure to pass the bill up to the delay on the more important

tariff legislation. The farm bloc, or rather what remains of the old farm bloc, are understood to be urging the passage of two measures: an agricultural credits bill, which it is agreed is badly needed, and the Ford offer for Muscle Shoals. None of these measures is apt to go through until the tariff has been completed.

Mexican Recognition Near

THE signing of a financial agreement in New York on the Mexican debt, between representatives of the Mexican Government and the group of bankers headed by Thomas W. Lamont means that recognition of President Obregon's government is near. If the United States recognizes Obregon, France and England are certain to follow. President Harding has denied that there was anything new in the Mexican situation, but business opinion seems to agree that recognition is imminent. This will, of course, have an influence on

those industrial concerns with Mexican holdings.

Coal Crisis Coming

THE crisis in the coal strike is expected to come after the first of July, when the retailers get back into the market under the influence of the reduced freight schedules. Then, too, the reserve stocks of soft coal at manufacturing plants are running low, and within another month some definite action may be expected. The Hoover agreement with retailers is expected to hold prices down to a reasonable limit until the strike has been definitely settled.

Car Shortage Coming

SINCE coal reserves are being steadily used up, when the strike comes to an end coal shipments will be abnormally large. This will cause an extra demand for freight

Badly Bumped.

(Indianapolis News)

in Perspective

cars at a time when the crop movement is under way and all available cars are used for wheat and corn. Furthermore, the lowered freight rates are certain to cause a steadily increasing volume of traffic, especially since an industrial revival of no small proportions is looked for in the fall. These facts all point to one conclusion—a serious shortage of cars next fall. The fact that new rolling stock is being rushed to completion does not alter the situation for a sufficient supply of new freight cars could not possibly be obtained in time to prevent the shortage.

Then, too, many cars not now in use, but in the railroad shops for repairs, may be kept out of use if a rail strike should follow, and this would have the effect of accentuating the difficulty.

The European Tangle

THE Genoa conference and the recent meeting of international bankers at Paris have not accomplished a great deal toward the rehabilitation of Europe, except to emphasize the seriousness of the economic situation there. The failure of the bankers to agree on a plan for a loan to Germany may be laid to the door of those French politicians who would willingly cut off Europe's nose to spite its face. It is possible that the Hague convention may accomplish some-

thing more, although it seems to be confusing politics with economics as badly as the Genoa conference.

Russian Reconstruction

THE problems in Europe are essentially economic and the intrusion of political principles to the exclusion of all others cannot but be disastrous. The question of international credits is at present treated in the light of political preference, and so long as this view of the matter is taken, little real improvement can be expected. The Russian problem is apparently as far from solution as ever, although practically all economists agree that the return of Russia into the markets of the world is one of the most necessary elements to European reconstruction.

The Summer Lull

BUSINESS all over the country is showing the usual summertime decline, and no improvement is expected until fall. If the coal strike is settled before then, and if the rail strike fails to materialize, industry will be well on its feet again by October. The passage of the Tariff bill will go far toward stimulating commercial activity, and it seems probable that another month will see it well on the road to completion.

We really don't need any more rain.

New England's Cotton Mills Fighting for Their Existence

The five months' strike of 50,000 employees in the New England mills is a symptom of economic affliction which results from the commercial advantages enjoyed by newer mills in the South

FIFTY THOUSAND cotton-mill operatives have been idle, and the industry in New England has been disorganized for nearly five months as the result of a strike that is more than a mere struggle between capital and labor. This conflict, which has stopped 10% of the cotton spindles in New England and caused a loss of production of more than 215,000,000 yards of cloth, is a symptom of a profound change in the conditions governing textile manufacturing. It is not simply a local dispute over wages; it is an indication that one of America's greatest industries is changing its location to a more favorable section.

The strike is a result of the competition between the cotton mills of the North and of the South. Manufacturers in certain parts of New England declare

that they cannot meet Southern competition without cutting wages, and they therefore announced the 20% reduction that caused the strike.

Since the 1880's the cotton industry of the South has been growing steadily. The invention of apparatus to humidify the air artificially in the mills so that cotton could be kept in the proper condition during the processes of manufacture, caused the industry in this section to advance with tremendous rapidity. Under the stimulus of war conditions it reached the point where it was consuming 55% of the cotton used in the United States.

COTTON manufacturing was formerly confined to localities where naturally moist atmospheric conditions permitted weaving and spinning. So our cotton mills sprang up in New England just as England's industry centered in Lancashire. But with the development of apparatus for artificially moistening or conditioning the air in the mills, new plants were built near the raw material source without regard to weather conditions. A row of one type of these small but important "weather manufacturers" can be seen just above the aisle in the weave-shed photograph at the top of this page. New England mills are struggling to maintain their supremacy by clinging to the manufacture of the finer grades of cloth, leaving the cheaper lines to their Southern competitors.

While the demand for cotton was kept up by the war and by the post-war boom the competition between New England and the South was not deadly.

There was a market for all the goods that both sections could produce.

When the slump came in 1920 the textile industry began to realize its position. Prices dropped perpendicularly, and the mills began to shut down. Then wage cuts were made. The New England mills successfully put into effect a 22½% general reduction in December, 1920. Labor disturbances and wage reductions occurred in the South also.

At the close of 1921 wages in both North and South, according to the best available estimates, remained about 100% above those which had been paid before the war. The Southern industry felt that the readjustment was fairly complete and that development could continue without further cuts. The New England manufacturers, however, were not satisfied. Hence, the attempts at wage reduction in the Pawtucket district of Rhode Island, later in New Hampshire and still later in Massachusetts, resulting in the present strike.

The story of the development of the cotton manufacturing industry in the South, and the advantages enjoyed over the Northern competitors, was told by George S. Harris, president of the Exposition Cotton Mills, Atlanta, in an address before the spring meeting of the Society of Mechanical Engineers:

"For a term of years our development was phenomenal," said Mr. Harris, "until today the cotton-growing States are making into yarn or cloth considerable more than half the cotton manufactured in this country. Of the 37,000,000 spindles

Not a snow factory, but a huge cotton-gin removing the seeds from the fibre. (© International.)

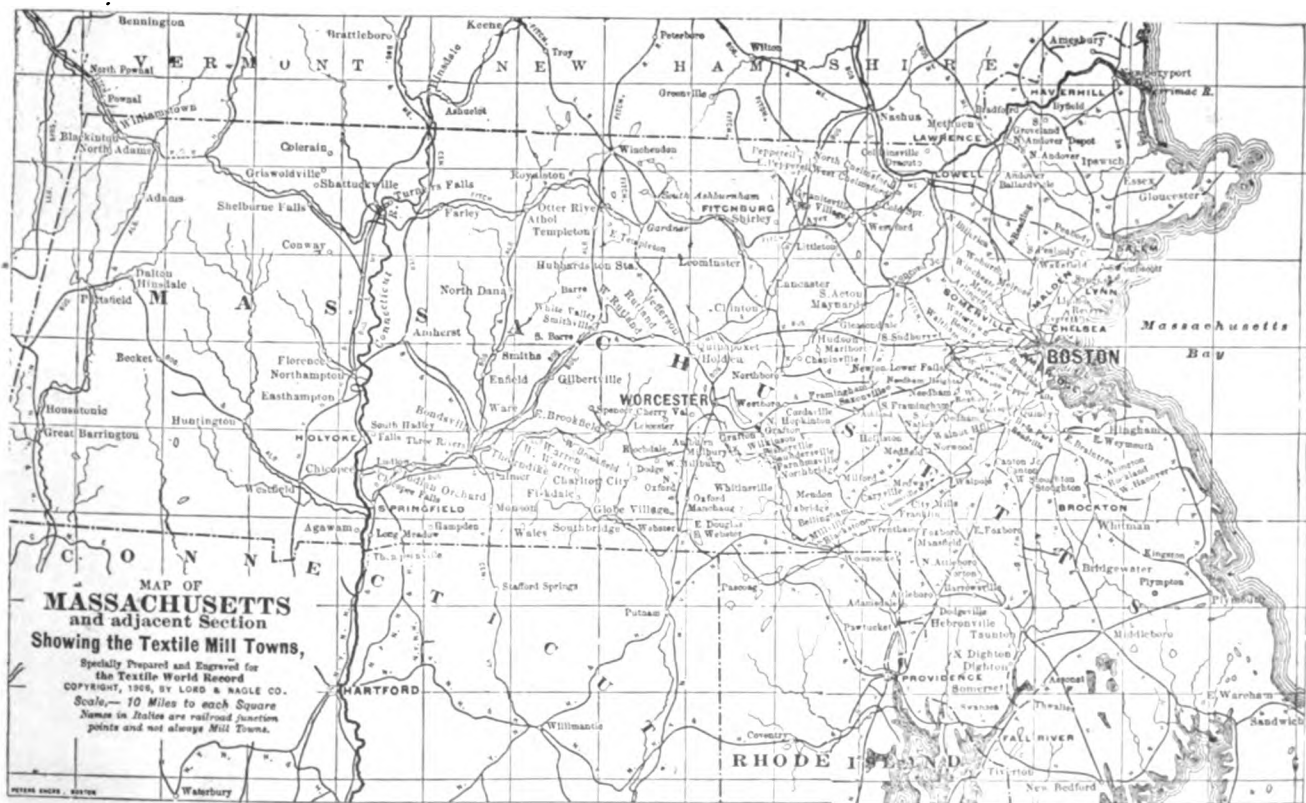

in the United States, the cotton-growing States have 16,000,000, or more than 43%. The mills of the cotton States are now consuming 55% of the cotton consumed in the country, with a steady increase.

"Before the successful development of the humidifying apparatus, cotton mills were confined to certain localities in which could be found natural atmospheric conditions permitting weaving and spinning. This very largely accounts for the large number of cotton mills in England and later those in our New England States. In the Southern States the hot, dry summer so necessary to the growth of cotton did not encourage the spinner, and the few mills we had in the old days were located on the banks of rivers for the dual purpose of supplying power and natural humidity. Some mills were scattered over the South, but the real growth was in New England."

Then came the development of apparatus for artificially keeping air in the mill at the correct degree of humidity and temperature. Mills no longer needed to be built to suit weather conditions. The South was the logical center for new mills.

"It might well be asked why the Southern mills advanced so much more rapidly than those in any other section, and I will attempt to answer, in part at least. We will take for comparison a mill in Georgia and another in Lowell, Mass., without any intention of discrediting what has been achieved by our friends of New England. As a matter of fact, we of the South marvel at their ability to show such financial results under their conditions.

"First, in the matter of cotton the Georgia mill has the advantage. When the mill in Lowell requires cotton it first deals with a local broker who will probably place the order

The textile area of New England, showing the present strike district.

King Cotton's Royal Road From

These pictures illustrate the landmarks, so to speak, on the royal road traveled by His Majesty King Cotton—a trip calling for much human effort and ingenuity.

In the corner is the cotton plant, which contains many seeds, and must first go to a cotton-gin (see page 1123) to separate seeds from fibre. Then begins the long process of transforming the shapeless fluff into strands of various thicknesses for manufacturing purposes. After it has left the picker (above) it goes to the card (at the right). Then comes the drawing frame (seen below), which pulls into fine strands (roving) the thick strands from the card (slivers). Another process is necessary on the slubbers (seen under the card) before the yarn is ready to be wound on spindles and sent to the spinning and weaving machines. The "mule" (lower right) is the machine that draws out the rough yarn and twists it into a strong, firm cotton thread. This same result can be accomplished by the American ring-spinning process (shown on the next page).

After cotton has gone through the processes shown on this page, it is ready for textile mills all over the country, one of the largest of which is shown below.

Photos by courtesy of the Guaranty Trust Co. of New York, The Textile World, Carrier Engineering Corp., Saco-Lowell Shops, Crompton & Knowles, and Brown Bros.

Plantation to the Finished Cloth

ring-spinning frame (shown at the right) performs the same duties as the French process, but does it quicker. It produces thread spun on the older "mule" is weaker and stronger.

Cotton compressed into bales for shipment. Perhaps the best-known symbol of American industrial life is the cotton bale, which goes by the millions annually to all corners of the globe.

A "close-up" of a roomful of ring-spinning frames in action (at left).

Below, is the ingenious warping machine which winds hundreds of warps simultaneously with fine cotton strands, all ready for the loom.

On the right is a type of automatic loom—perhaps the busiest of machinery in America. The old intricate looms with their complicated and clumsy mechanisms have given way to these new high-speed automatic looms—and produce better cloth faster and finer than the old machinery.

After the automatic loom has its inning, the finished cloth must be inspected. There is small resemblance between the material seen in the corner below and the blossom in the upper corner of the left page, but the process has been completed; and the next step is an order to the tailor.

Another type of automatic loom. Automatic control and control are in these machines. Electrical control detects imperfections such as the breaking of a thread, and stops the machine. The ducts in the loom are found for keeping the air so that the cloth may be done in the most favorable conditions.

with one of the many cotton shippers maintaining a large organization covering more or less the entire cotton belt. These shippers in turn will buy the cotton from smaller shippers operating in one locality who might buy direct from the producer or from a merchant who has taken in cotton on account of supplies furnished during the growing season. The cotton, before it can start on its journey, is concentrated at some point for compression. Here it receives considerable handling and is compressed to a high density. By the time it reaches New England it not only has accumulated a very high freight charge, but the percentage of tare has been increased at the compress.

"In contrast to this long process with its three to four necessary profits, the Georgia mill will buy generally from the local shipper and might buy directly from the large responsible producer, with transportation cost usually only a few points. In addition to this, the mill in Georgia can handle uncompressed cotton, saving the extra tare and expense incident to compressing, besides the extra mill expense in opening compressed cotton. I have never been in a position to make a dollar-and-cents comparison of this cost of cotton, which would naturally vary with the seasons, but the difference must always be there and in some seasons it must be considerable.

"The labor cost has always been in favor of the Georgia mill, due as much as anything else to climatic conditions. The long, hard winters of the North necessarily make the cost of living very materially higher, which must be borne finally by the manufacturer in his payrolls. In the South from the beginning the mills found it necessary to provide homes for the operatives as this proved to be a decided economic advantage, both to the mill as well as to the operative. The village plans today are given the same consideration as the mill plans in the original layout. This has given the operative a far more comfortable home at a much less cost to the mill than if supplied by outsiders who haven't the same interest in the operatives or the mill. Furthermore, this scheme of things has tended to keep the relationship between employer and employee closer. Contrast this with the operative in New England who lives in a house probably one or more miles from his work and which he rents from a landlord who has no interest in him beyond that of keeping his property occupied profitably.

"There was a time when this was very largely offset by the higher efficiency of the labor in Massachusetts, but this advantage has now been shifted about. With every year our labor has been growing more and more efficient, while the original superior labor of Massachusetts has been replaced each year at a steadily increasing percentage with untrained immigrants.

"In contrast to this, in a Georgia mill is a class of labor, all American, recruited from the farming class. The manager has grown up with them and knows them in their homes. In many cases the mill, being a comparatively young institution, was built from a small unit by the present owners. The manager, living in close touch with the labor, is in a position to talk freely with them. I know of instances in Georgia, during the recent depression, where values depreciated so fast that it was impossible for a mill to continue operating without tremendous losses, but the employees quickly sensed the entire situation and voluntarily submitted to reductions in their pay in order that the mill might continue to operate. Do you hear of such actions in the mills of New England? I have not. The result is that while the Georgia mill is in position to sell its product today in line with the depreciated value of raw products, the New England mill has its manufacturing cost held up fictitiously and is forced to take heavy losses in current values or shut down."

When the strikes in New England started last January the Northern manufacturers were careful to point out the advantages enjoyed by the South. The Southern manufacturers

Diagram of cloth printing machine—(a-b) cloth, (c) engraved rollers, (d) main cylinder.

endeavored to minimize these advantages and there was not a little heated verbal controversy on the subject. Edward Farnham Greene, a spokesman for the New Englanders, made a public statement pointing out that wages in the South were considerably lower than in the North, thus drawing upon himself the fire of Winston D. Adams, secretary-treasurer of the American Cotton Manufacturers' Association, of Charlotte, N. C. Mr. Adams contended that the cost of maintaining workers' villages in the South brought wages there virtually to the same level as that prevailing in New England. He quoted the National Industrial Conference Board as follows on average weekly earnings of textile operatives in both sections:

The figures show a slightly higher percentage of increase

in the North.

	South	North
1914	\$7.10	\$9.02
June, 1921	13.99	18.71

And he added that the American Cotton Manufacturers reported that the company villages, in which cheap rent, free light and fuel are supplied to the worker, cost the manufacturers of the South \$4.36 a week per operative in addition. This would bring the Southern wages up to \$18.35, only 36 cents less than the Northern wages.

The New England manufacturers, however, refused to recognize this point of view. The Amoskeag mills at Manchester, N. H., in announcing the wage cut that caused the employees to walk out on February 13, said: "The textile manufacturers of the North, if they are to continue to operate, must meet the competition of the South, where the wages are 50% to 60% of those in the North, and where the working hours are from 55 to 60 hours a week." Later the company explained its position as follows:

"Working 48 hours a week, with wages at last year's levels, the company cannot turn out goods in competition with Southern mills. In consequence, many of the standard Amoskeag brands are being produced elsewhere at a lower cost, and it has been necessary to discontinue making them. . . . The peril of the South is that in 1900 it had 5,500,000 spindles; today the number is 15,949,000.

"In the last 20 years the number of spindles in Northern mills has increased from 15,700,000 to 20,776,000. The difference in rate of growth is largely due to the fact that at least 90% of the Southern mills are running on a minimum schedule of 55 hours a week, and many of them are operating 60 hours weekly.

"During last December, Southern spindles ran 239 spindle hours, as compared with 188 hours in Northern mills. In other words, Southern spindles were operated on an average of 11½ hours more a week than were the Northern spindles. . . . In an industry where competition is keen, this factor alone is fatal, for the fixed expenses, which amount to large sums yearly, remain the same whether the mills run 49 or 54 hours a week. By running 54 hours these expenses are reduced ⅛—the difference between life and death to a business dependent upon a large output and a narrow margin of profit."

These statements, of course, were intended to put the difficulties of the New England textile manufacturers directly up to labor. What has labor to say about it?

The unions replied that Southern competition was a bogey raised by the manufacturers for the express purpose of oppressing their workers. "We are prepared to show," said

Thomas F. McMahon, president of the United Textile Workers, "that where Northern mills claim they have Southern competition these Southern mills are mostly controlled by Northern capital."

The union, according to Edwin Newdick, writing in *Labor Age*, made the following statements in paid advertisements attacking the propaganda of the mill owners:

"They showed that Amoskeag's capitalization has been increased from \$4,000,000 to over \$44,000,000 without contribution of a single dollar, except from profits.

"They showed that Amoskeag now has in surplus and quick assets a total nearly equal to its entire capitalization.

"They showed that Amoskeag paid out nearly \$3,000,000 in dividends in the 'bad' year of 1921.

"They showed that Amoskeag paid out 409% more in dividends in 1921 than it did ten years before, in 1911.

"They showed that Amoskeag earned in net profits 139% more in 1921 than it earned in 1911.

"They showed that Amoskeag paid out in dividends in 1921 about \$1,250,000 more than it earned—withdrawing the balance for dividends from surplus.

"They showed that Amoskeag made 139% more profit in 1921 than in 1911 on the sale of only two-thirds as much cloth.

"They showed that \$100 invested in Amoskeag 25 years ago would have yielded \$670 in dividends to date.

"They showed that \$100 invested in Amoskeag 25 years ago would also have yielded its possessor stock now worth \$1175.

"They showed that the profits of Amoskeag per dollar of sales averaged 47% higher in 1912-1916 than in 1907-1911.

"They showed that the profits of Amoskeag per dollar of sales were higher in 1921 than the five-year average of 1907-1911.

"It was shown that, during the last 20 years, all the Fall River mills, for which financial records were available, including 26 of the largest mills, had averaged 8.4% on capitalization.

"Figures were presented covering the earnings of every textile mill in Fall River whose stock is listed, 36 in all, showing the profits from the beginning of 1917 through the first quarter of 1922. At this very time when the industry of New England is screaming for help, shaking with palsy at Southern competition, cutting wages and begging for longer hours, these 36 Fall River mills averaged for the first quarter of 1922 dividends totaling over 11% per annum on their capitalization. This capitalization has been increased by more than

25% since the beginning of 1917, practically all by stock dividends, that is, capitalization of profits.

"Since the first of 1917, these 36 Fall River mills have paid over 83% cash dividends on their capitalization. On their capitalization of January 1, 1917, these mills have paid since that date cash dividends of 96.97%. That is, the stockholders of these Fall River mills have received in cash, dollar for dollar, virtually the full capitalized value of the properties since January 1, 1917—more, in fact, if allowance is made for any interest on dividend money deposited or reinvested."

It will appear immediately to most business men that, even if these statements of the union are true, it does not follow that the Northern cotton mills can continue their present wage scale and yet stay in business. As long as the demand for cotton cloth is less than the combined output of both Northern and Southern mills, the mills which can operate least economically will be forced out. It doesn't matter how large the dividends were that those mills formerly paid. It doesn't matter if the mills made 500% profit last year. If their costs are higher than costs elsewhere, and there is keen competition for a market, they must cut their costs or quit.

Northern Mill Owners' Viewpoint

THE New England mills, realizing this, have refused to arbitrate the wage reduction. They have stood firm, declaring that their business life is involved. In a statement rejecting Government offers of arbitration they said:

"The question of wages in the present state of cotton manufacturing is simply a question of keeping the cost of goods produced by our mills within the price for which that product can be sold. Unless we can do this at once we must very soon close our mills. It is not a question of reducing wages to increase profits, for in most cases there are no profits nor have there been for months past, nor will there be, so far as we can see, for an indefinite period to come.

"It seems to us that it would not be fair dealing to agree to arbitration when we know that we could not, if we would, carry out its award, if that award increased the wage scale which we have offered.

"The scale of wages that it is possible for industry to pay cannot be determined academically; it is fixed by conditions

(Turn to page 1180)

"The hall of a thousand looms" is not a figure of speech in this cotton mill in Lawrence, Mass. There are actually a thousand looms within the area shown in the picture. (© Galloway.)

Will There Be a Rail Strike?

More than a million men will be affected by the wage reduction—
rail workers join forces with miners to fight cuts

WILL there be a rail strike on July first? Or will the rail workers affected by the recent decisions of the Railroad Labor Board decide it is wiser to accept the cut in wages than to gamble on the chance of winning the strike?

The wages of 1,225,000 railroad men were cut by an annual amount totaling \$135,000,000 by the recent ruling of the Labor Board. First the 400,000 maintenance-of-way men were affected by a ruling reducing their wages \$48,000,000 a year. Then 500,000 members of the shop crafts unions were notified that their wages were to be cut \$60,500,000 a year. Finally, the 325,000 clerks and station men on the country's railroads were advised that a reduction of \$26,500,000 would go into effect July first.

The leaders of the various rail unions, though expecting that some reductions would be made, were surprised that the wage-cuts were so large. The union executives immediately protested and prepared to take a strike ballot to determine the attitude of their members toward fighting the order.

In a letter to the Railroad Labor Board, signed by B. M. Jewell, president of the Railway Employees Department of the American Federation of Labor, and by the president of the ten associated unions affected by the rulings it is asserted that the decisions of the Labor Board constitute a clear violation of the provisions of the Transportation Act.

"The right to at least live is fundamental," says the letter, "but your decisions deprive a large number of railroad workers of even this elementary right. Men in America cannot be expected to work for public utilities only to see their children undernourished and doomed to a premature death, or if they do survive the almost intolerable conditions imposed by your decisions, to be destined to go through life without an education or the opportunity to realize a healthy and decent existence. . . . Your further statement that you will give consideration to the living-wage principle when the railroad properties are financially rehabilitated is not reassuring. You thus give further confirmation of the fact that your entire attitude is one of subordination of human rights and standards to property rights. Moreover, the necessity of living cannot be deferred. The Congress or the people of our country do not expect railway employees to be exposed to poverty, starvation and suffering, pending the time when the railroad bankers have rehabilitated the railroad property at the expense of the public, and of the railway employees. In this connection, we are also reminded of the fact that in May, 1920, when the volume of traffic of the railroads was unprecedented, you refused to give consideration to our request for a living wage.

"Railroad labor costs have constantly declined during recent years. High operation costs are due to the delinquencies of financial control. If the capital needs of the railroads were financed by the public and they were operated in the public interest, freight rates could be greatly reduced and wages to employees increased to the point where "living" and "saving" standards of life could be maintained. . . .

"Our attitude from the time the Labor Board was established up to the present has been, as you know, that in determining the wages of railway workers the Transportation Act assumed that the Labor Board would adopt the following basis of procedure:

"(1) That the section men, laborers and others at the bottom of the scale of occupation should receive a living wage, as the term is ordinarily used, or an amount sufficient to maintain themselves and their families in comfort and decency;

"(2) Other employees should receive differentials above this amount, extending upward, according to skill, hazard, responsibility, training and experience."

Similar expressions came from other union executives. But the following figures, which the Railroad Labor Board used in determining the extent of the cut, were quoted by those members of the board who rendered the majority report.

The Cost of Living in the Labor Board Decision

BASED upon the evidence before the board, the statistical department of the board has made a study of the

comparative purchasing power of the wage herein fixed for certain of the shop crafts and the purchasing power of the wage paid such employes on the railroad in December, 1917, immediately prior to Government control of the carriers; in January, 1920, just prior to the termination of Federal control; on May 1, 1920, the effective date of Decision No. 2; on July 1, 1921, the effective date of Decision No. 147, and in March, 1922. The results of these studies are as follows:

Average Hourly Rates

	Machinists.	Car Men
December, 1917.....	50.5c.	37.7c.
January, 1920.....	72.3c.	68.0c.
May, 1920.....	85.3c.	81.0c.
July, 1921.....	77.3c.	73.0c.
Under present decision.....	70.3c.	64.4c.

Percentage of Increase in Average Hourly Rates Over December, 1917

January, 1920.....	43.2%	80.4%
May, 1920.....	68.9%	114.6%
July, 1921.....	53.0%	93.6%
Under present decision.....	39.2%	70.8%

Haunted by the perpetual ghost.

(Columbus Dispatch)

Increase in Cost of Living Over December, 1917

January, 1920.....	40.0%
May, 1920.....	52.0%
July, 1921.....	26.7%
March, 1922.....	17.2%

Percentage of Increase in Purchasing Power of Earnings of Subsequent Dates as Compared with December, 1917

	Machinists	Car Men
January, 1920.....	2.3%	28.8%
May, 1920.....	11.1%	41.3%
July, 1921.....	20.8%	52.8%
Under present decision.....	18.8%	45.7%

Although average hourly earnings of machinists are below the earnings after Decision No. 2 was applied, by 15 cents per hour, their value is 6.9% greater due to the decrease in the cost of living.

The average hourly earnings of car men are below the earnings after Decision No. 2 was applied, by 16.6 cents per hour, but their value is 3.1% greater for the same reason.

The cost of living figures set out in the foregoing tables have been compiled from the reports of the United States Department of Labor and are for the latest date for which such data are available.

The most serious factor in the situation is the possibility that the rail and mine unions may combine to fight the reduction. The railroad unions and the miners have an agreement which provides:

"When it becomes apparent that any one or group of our organization is made the victim of unwarranted attacks it will become the duty of the representatives of each organization to assemble and devise ways and means to be applied to best meet the emergency."

Both the miners and the railroad workers, who have suffered wage cuts, believe they have been the victims of unwarranted attacks, consequently a conference has been held with a view to consolidating the two groups.

But that a return to normal industrial conditions cannot be expected so long as the present wage rates are maintained is the belief of the Railroad Labor Board, for the reason that railroad wages not only affect transportation costs but industry and production in general. In the recent ruling it was stated that in order to secure efficient service from the carriers it was necessary to give them an opportunity to profit by the revival of business so that they might expand their facilities. A strike, it was asserted, would not only result in losses to the rail workers and the carriers, but would likewise retard business recovery. Some members said that it would also defer the scientific adjustment of the "living and saving wage" to which the board in its decision said it could devote greater consideration when the "abnormalities" of the present time were over.

In a recent statement issued by the presidents of six Chicago railroads, it was asserted that all threats of a walkout were being inspired by union leaders. The statement was signed by H. E. Bryan of the Chicago, Milwaukee & St. Paul; Hale

Holden, the Burlington; W. H. Finley, the Northwestern; J. E. Gorman, Rock Island; C. H. Markham, Illinois Central, and S. M. Felton, Chicago Great Western, and follows in part:

"Threats of a strike, made by leaders of the railroad labor unions, are appearing with such frequency that the time seems opportune for questioning the soundness of their talk. There is a very good reason for doubting whether the men themselves, that is, the railroad employees, really are in sympathy with resistance to the decisions of the United States Railway Labor Board.

"The public should not overlook the fact that in deciding the proposed wages of these employees, maintenance of way and shop, the Labor Board, which is a Government body, said 'after the reductions made under this decision—these employees in the railroads will be receiving, as a rule, a wage in excess of that paid to similar employees in other industries.'

"The board held in its opinion that measured by the present cost of living, the average hourly wages of machinists, for instance, after July 1, will still have 19% more purchasing power than in December, 1917; those of car men, 46% more purchasing power, and those of common laborers 45½% more. That is to say, measured by the cost of living, their wages will still be these percentages higher than at the end of 1917.

"An important fact which should not be overlooked by the public, because it may have a very important bearing on its business and comfort, is that whereas State reductions amounting to more than \$250,000,000 have been ordered by the Interstate Commerce Commission the cut in wages, according to the decisions thus far rendered, amounts to only \$110,000,000.

The situation, as far as the public is concerned, was further complicated by the agreement on June 20 between the presidents of the United Mine Workers and the Railway Employees' Department of the

A. F. of L. to act in a "concerted economic action combatting wage reductions." Details of the plan were not made public, but the announcement said "We have no other recourse." If the plan goes through nearly 2,000,000 railroad and mine workers will be affected.

Although labor leaders assert there will be no compromise, it is regarded as significant that during the A. F. of L. convention at Cincinnati, there has been little discussion of definite plans for carrying on the strike. Although labor leaders speak of more than 1,000,000 being affected by the strike vote, when pressed for details, such as the names of the roads on which strike orders are expected to be issued, or the crafts on these roads, to which they will be issued, no information was forthcoming.

It is believed by Ben W. Hooper, the chairman of the Railroad Labor Board, that the railroads will voluntarily discontinue contracting out work in a short time, regardless of their opinions as to its legality, and that this will go a long way toward restoration of cordial relations between the carriers and their employees. He points out that neither wages nor rates are permanent because the conditions on which they were based are not permanent.

The rail workers know, too, that the sentiment of the public is against strikes, and that the fact that employees in other industries have taken cuts weakens their own case with the public.

Railway employee earnings and cost of living. In July, 1920, it cost about \$210 to buy as good a living as could be bought for \$100 in 1914. The average railroad employee, however, although working fewer hours, earned \$221 for every \$100 he received in 1914. If he had worked at the same rate for as many hours as he did in 1914 he would have made \$268. In February, 1922, it cost only \$162 to buy as good a living as could be bought for \$100 in 1914. The average railway employee actually earned \$186 for every \$100 earned in 1914, but would have received \$252 if he had worked the 1914 hours at the same rate.—(Index.)

Now Is the Time to Invest Abroad

Never have conditions so thoroughly justified the employment of American capital in Europe. The question is, How shall the money be spent?

THE field of foreign investment at the present time seems to offer greater opportunities to American capital than at any previous period in the history of the nation. Europe is desperately in need of capital, and we have surplus funds for investment. This situation of supply and demand, even if it were not attended by other favorable conditions, would make the time auspicious for the development of our financial interests abroad.

But foreign investment of American capital now means more than the carrying of surplus funds to a market that will pay well for the use of them. It will serve, in addition, three purposes:

First, it will contribute to the clearing up of the international industrial and financial situation, and thereby aid the recovery of American industry;

Second, it will pave the way for the payment of Europe's war debts to the United States;

Third, it will help America to obtain a lasting foothold in the markets of the world, so that our industries may always be able to dispose of their surplus products abroad.

One simple way in which the investing of American funds abroad will aid American industry by helping to clear up the international financial situation was explained in these words by an economic expert employed by one of New York's largest trust companies extensively engaged in international finance:

"Suppose France negotiates a \$100,000,000 loan in the United States. A credit of \$100,000,000 will be placed to the account of the French borrowers in New York banks. They will collect their money by buying franc exchange in the New York market, which will send the franc up. This will benefit American industry, for it will remove one of the obstacles to the recovery of our export trade, the low value of foreign money in terms of dollars. It will be easier for the French to buy here, for they will get more dollar value per franc.

"The actual transfer of the \$100,000,000 from this side of the Atlantic to the other will be made partly in American goods and partly in gold. A certain amount of gold will be shipped in payment as long as the difference between the par value of the franc and the value of franc exchange in New York is greater than the cost of shipping a franc's worth of gold bullion. This movement of gold will benefit Europe, which needs more of that metal in order to stabilize its domestic currency, and it will not hurt the United States, which has more gold than it can use. The shipment of American goods will also help America, of course, and the approach of European currency to stability will also react beneficially on American trade."

What American Money Can Do

MORE important than this purely financial aspect is the effect that American investments abroad may be expected to have on the reconstruction of Europe's industry. American money can be used to rebuild factories which can help Europe to return to prosperity and help her to pay her debts to us. *Barron's Weekly* discusses the European debt problem as follows:

"At the present time the debt of Europe to the United States cannot be less at the most conservative estimate than \$12,500,000,000. Interest alone on this vast sum at the low rate of 4%, less than any of it actually bears, would require \$500,000,000 a year, more than the average 'favorable' balance of trade of the United States with all the world in the first decade of the present century. How shall this great amount of interest, to say nothing of any payments on the principal, be paid?

"It must be clear that payment in goods is impossible, at least for some time to come. The United States comes very close to being self-sufficing economically. We can supply ourselves with raw materials and with manufactures independently of the outside world. There are a few luxuries, a few raw materials, a few manufactures which we shall buy from Europe, but they are more than balanced by the goods which Europe must have from us, leaving nothing to apply on interest or principal of the debt. Of gold we have more than our share already. Europe may pay something in services, particularly in transporting our products over all the seven seas in European bottoms. The determination of the American people to have their own merchant marine, however, probably means that we shall have less use for these services today than before the war.

"In the long run, we must take our pay in goods if at all, but it is evident that the economic dislocations involved in a sudden shift of the balance of trade make it imperative that the change be brought about gradually. In one way only is this possible—through the medium of foreign investments of America's great wealth. By exporting capital in large amounts we shall enable our debtors to reconstruct their shattered economic and financial systems, regain their pre-war earning power, place themselves upon a basis where the repayment of their debts to us will be possible for them and convenient for us."

"Bread on the Waters"

THE third way in which the investment of American capital abroad will benefit our industry is by enabling us to obtain a foothold in the markets of the world. England and other nations which in the past have played dominating parts in the world trade have used their financial advantages to help their exporters. The presence of English capital in China, for instance, makes it easier for Englishmen to sell goods there. If you own shares in the factories of a foreign nation your attempts to supply them with their raw materials or with semi-finished products for further manufacture will certainly be facilitated. An opportunity to place herself in such a position is now before the United States.

Most of the opportunities for foreign investment that have been placed before American investors up to the present time have been government bonds. The greatest opportunity, however, does not lie along these lines, but in the purchase of securities of foreign industrial corporations.

Not many loans to foreign corporations have yet been floated in the United States. The first important attempt along this line, according to *Barron's Weekly*, was the flotation of a \$15,000,000 issue of Central Argentine Railway convertible 6s, 1927, offered to the American public just before the United States entered the war. This offering was not very favorably received, in spite of the facts that the Central Argentine is an especially profitable property and that investments in Argentine rails have been among the most successful ventures of British capital abroad. The coldness of the public to this loan, and the preoccupation with United States Government financing that followed our entry into the war prevented further attempts along this line. In 1922, however, investment bankers began once more to sell foreign corporation bonds here. The list of offerings, all of which were successful, includes bonds of an Australian public utility, a Brazilian railway, a French steel corporation and a Dutch shipping concern. More such offerings will undoubtedly be made in the immediate future.

From the point of view of developing markets for American industry the entrance of American capital into manufac-

turing ventures abroad is more important than investment in bonds. American corporations have already done much in this direction. The International Harvester Company has factories in many foreign countries, including Russia, and Ford maintains plants in Europe. The big packers own property in South America. Two American manufacturers of jute bagging and twine have opened factories in India, near an important source of their raw material. Building construction work in the East has been undertaken by such engineering concerns as Stone & Webster and the George A. Fuller Construction Co. The Standard Oil Co. of New Jersey has interests all over the world, and Chile Copper is helping to exploit the mineral resources of South America.

"With increasing intensity of competition for world trade, it may be expected that American corporations will extend their operations on foreign soil to a still greater degree, with profit both to themselves and to the nations in whose development they will thus assist," says *Barron's Weekly*.

Even less has been done in the way of selling shares in foreign corporations to the general American investing public than in selling loans of such corporations. Kuhn, Loeb & Co., however, has achieved something along these lines. Since 1916 they have issued and sold blocks of stock in the Royal Dutch Co., the Shell Transport & Trading Co. and the DeBeers Consolidated Mines, Ltd. They used the method of issuing "American shares" in these foreign corporations against the deposit of the original stocks of the companies with an American trust company. Dividends on the "American shares" are payable in dollars equivalent to those received by the trust company on the original shares. In no case do the "American shares" represent more than 10% of the total capitalization of the foreign corporation.

Not long ago some of the stock of the Rotterdam Bank was successfully offered unchanged in form to the American public. Another form of foreign investment is illustrated by the purchase of cotton mills in Szecho-Slovakia with a capacity of more than 200,000 spindles by a group of New England business men.

U. S. As World's Investment Leader

THE United States has already obtained a good start toward becoming the world's greatest investment nation. That position is now held by Great Britain, but America is gaining rapidly. We have been absorbing large quantities of foreign government securities for a longer time than most persons realize.

"From 1904 to 1913 foreign government notes and bonds floated in New York aggregated nearly \$300,000,000, of which about one-half were Japanese loans issued in sterling," says a report of the National Bank of Commerce. "This total does not include Canadian municipal securities, which were absorbed in large amounts by this market. The war diverted the course of international finance from established channels and increased the needs and borrowings of other nations from the American market, but the developments under peace conditions would have been along similar lines.

Volume of foreign financing in the United States and in the United Kingdom, in millions of dollars (pounds converted at current rates of exchange).—(Federal Reserve Bank, N.Y.)

"Below in the tables shown is summarized the reported external financing carried out in the United States from 1919 to 1921.

"America will not have matters all her own way in world finance. There is severe competition ahead. Improving money conditions abroad, particularly in London, where there has been a marked lowering of rates, will increase effective rivalry with this country.

The favorable position of the dollar among the currencies of the world has made foreign borrowings here particularly advantageous in the past few years, but as the premium on the dollar declines, this advantage will be reduced.

International competition demands the further development in America of sound foreign investment experience and judgment, the training of skilled personnel to handle this business, and, above all, it will demand particular discrimination to guard the American investor against unwise securities.

On that basis only can a substantial and enduring capital market be maintained in the United States."

	1919	1920 (000 omitted)	1921
Foreign government other than Canadian municipals..	\$514,679	\$291,000	\$385,270
Canadian municipals	93,637	53,278	75,982
Municipals of U. S. possessions	11,700	16,277	25,274
Totals	\$620,016	\$360,555	\$486,526

"The tendency of the American market to absorb increasing amounts of foreign issues is shown more clearly in the following figures, showing the growing amount of new money in the above totals:

	1919	1920 (000 omitted)	1921
Refunding	\$359,129	\$107,498	\$50,000
New loans	269,887	253,057	436,526
Totals	\$620,016	\$360,555	\$486,526

The opinion has been expressed in American industrial circles that foreign government loans should be floated in this country only on condition that the money so raised be spent here. American manufacturers are hard-headed men, and many of them see no reason why this country should lend money abroad to be spent abroad. They want to be assured by a clause in the loan agreement that this country will benefit by the loan.

The international bankers who are most directly interested in fostering America's foreign investments do not believe it would be sound economics to lend money with strings on it. They feel that Europe will get more benefit from a loan if she is permitted to spend the proceeds wherever she can to most advantage to herself; and they argue that anything that will increase the speed of Europe's recovery will help us more than we could help ourselves by forcing Europe to buy of us against her own true advantage. Further, they say that the tangle of international exchanges and currencies will not get the full benefit of the loan if it is encumbered with provisions as to where the money shall be spent. Finally, the bankers say that if we insist on such conditions Europe will simply try to get along without our money and the opportunity will be lost.

Who Advises You on Investments?

Do you place money in a business on advice of your lawyer, banker, a "business friend" or a certified accountant?

"IT'S surprising how much trouble the average business man has with his investments," said the certified public accountant. "If he finds himself with a little capital beyond the requirements of his business he runs into all sorts of difficulties in the attempt to place it properly."

"More often than you suspect, a man who is unusually clever in his own line gets stung when he tries to invest on the outside. I am not speaking of the man who is content to lend his money at the prevailing rate of interest with unimpeachable security. Most business men are not satisfied with that. They get more for their money in their own business, and, being business men, they naturally think they ought to be able to get more for their money under all circumstances. Government bonds and securities legal for savings banks are all right for widows and orphans, they think, but for men with an understanding of the business world better things are available."

"But a good business investment is hard to find, and most men are not equipped for the search. They flounder around, following up tips offered by their friends and asking their attorneys to investigate this, that and the other proposition, and often they end by making an investment they are sorry for later or by deciding that securities good enough for a widow are good enough for them, too."

* * *

Indications of the truth of these remarks may be found in the "Business Opportunities" columns of the newspapers. Persons who advertise for capital these days get replies in large numbers. They don't always get the capital, but they are sure to get plenty of interviews with business men who have capital to invest, and wish to look into the proposition advertised. If you don't believe this just insert an ad reading

INVESTORS with \$10,000 each wanted to back an established business that is ready to expand. Successful record. Investigation invited. S-567 Bugle, Downtown.

and see how many replies you will get. If you have inserted the ad in the right newspaper the chances are ten to one that you will find a dozen or more persons who are willing to accept your invitation to investigate.

The extraordinary activity these days of promoters with new stocks to sell is another indication of the large amount of money that business men now have on hand to invest, and the difficulties they are experiencing in finding suitable places

for their capital. The stock promotion game is flourishing now to an unprecedented extent. It grew great during the past year just as the bucket-shop business grew; but unlike the bucketing trade it has not been seriously damaged by public clamor. Its high priests operate in richly equipped and spacious temples, in some cases occupying several floors of large New York office buildings, from which they send out hundreds of high-power salesmen, trained by the latest methods of inspirational sales-education, to gather in capital seeking investment.

They do a legitimate business, selling shares in new enterprises. They don't, of course, tell their customers how small a proportion of the new enterprises launched each year ever become successful; but of course you cannot expect a stock salesman to tell his customers any such thing. And any one of these promoters will tell you, and back up his statement with evidence, that he is not selling exclusively to ignorant immigrants, but that a large part of his clientele is made up of business men.

The reason for this, of course, is the same as the reason for the increased activity in the markets for established stocks and bonds. The slackening of trade has released for investment large sums which otherwise would be more profitably employed in the investor's own business.

How does a business man go about his quest for a profitable investment outside of his own business?

How Business Men Invest

HE can go to a business broker, who is interested in getting his money from him and whose advice is therefore not to be relied upon entirely. He can ask his business acquaintances if they know of anything, but their judgment is not always to be trusted. He can ask his lawyer to investigate a proposition for him. He can seek advice from his banker, who will probably recommend that he keep away from "business opportunities" and buy conservative bonds. But none of these methods is quite satisfactory to a business man who feels, quite rightly, that he should be able to find a sound investment for his surplus funds that will hold out to him the

(Turn to page 1180)

These charts shed interesting light on pre-investment activities. The bar "No one, 48%" and the segment "Partly, 34%" should be considerably reduced.

Farmers As Factory Employees

Will industry turn to the country town as the ideal location for manufacturing plants so June farmers may be December mechanics?

WHAT would you give, Mr. Manufacturer, if you could have a steady supply of labor available at your busy season, out of your way in slack times, always consisting of the same contented personnel, and living happily on an income that is not entirely derived from you? Wouldn't that be a fairly satisfactory state of affairs?

But perhaps your labor problem has already been solved. Perhaps you are so much luckier than the rest of us that you can always get the right kind of hands at the right price whenever you want them. In that case you needn't bother to read this article, which is a discussion of a visionary scheme for helping to cure the labor troubles of American industry, and at the same time help solve the farm problem, the problem of city congestion and perhaps a few more of the difficulties of civilization.

The author of the idea is Henry Ford. Mr. Ford's mind is productive of many ideas for the solution of the world's troubles. Not all of his schemes are regarded highly. But in discussing any idea of his relating to the labor problem it is worth while to remember that Mr. Ford is a highly successful manufacturer, and that his record for success with his own labor is hard to beat.

Mr. Ford's scheme is this: Let us combine factory work with farming. Let us locate our plants in country neighborhoods, and encourage our employees to own and operate farms. With the aid of modern mechanical methods they will be able to finish their agricultural duties in a short period every year, and they will have the rest of their time for factory labor. They will thus be stably attached to the plant, able to make a part of their living outside the factory, and relieved of the monotony of continued work at one job.

In an interview with Bernard L. Johnson, editor of *Farm Mechanics*, Mr. Ford explained his scheme, speaking, of course, from the farmer's point of view.

"The time will come when every farming community will have its local shop and industry where the farmers can employ themselves productively for the 200 days and more each year when there is no work to be done on the farms.

"As I see it, the farm homes of the future will be grouped in villages where modern conveniences can be enjoyed cheaply and where the workers can find profitable employment about nine months of every year when there is nothing more to do out in the fields. In the spring and again in the fall, when field work is to be done, the tractor and implements will be loaded onto motor trucks and quickly hauled to the job. The work will be quickly done and the implements returned to proper storage."

It is hardly fair to call this idea a scheme. It is rather a prophecy, setting forth what may be expected to take place in the natural course of events—a favorable situation, the advent of which can be aided by those who would benefit by it.

It is a vision. It seems unreal, and yet it is not unrelated to the facts. The application of machinery to farming has actually made it possible, under favorable conditions, to get farm work done in time that would have seemed unbelievably quick to the last generation. Our cities are uncomfortably overcrowded, and the last Federal census seems to indicate that the flow of population to the cities, while not checked, is at least slowing down. There is an increasing tendency for industrial concerns to locate in country districts. Farmers are taking more and more interest in things outside of their immediate sphere. All these facts dovetail with Mr. Ford's idea, and indicate that perhaps the trend is actually in the direction which he indicates.

Not far from his automobile factory Henry Ford runs a farm along the lines of his vision. Men from the factory are sometimes employed on the farm, and vice versa. By using plenty of machinery he gets his farm work done in record time. Last year he harvested a 2,500-acre crop of winter wheat in five and one-half days. Behind the tractors that drew the reapers was a line of plows, and as soon as the crop was in the barns the fields had been turned over for the next year's seeding, and the labor that had done the job was available for a winter's work making automobiles.

Is it feasible to locate industry in the country? Why not? A factory must, in most cases, be on a railroad and conveniently located in regard to its sources of raw materials and its market; but these conditions can be, and often are, fulfilled in locations near good farm lands.

When large corporations create towns in which their workers can live they usually encourage the men to cultivate little garden plots behind their houses. There is a great difference, of course, between a garden plot and a farm, yet to urge workers to grow their own cabbages is a step, however small, in the direction of Mr. Ford's ideal condition.

If that condition could be made to prevail, it would be wonderfully beneficial for all hands. It would mean satisfied, cheap labor for the manufacturer and a fuller, happier existence for the combined farmer and factory worker. It is a vision for the future. Mr. Ford's idea may or may not be practical. It is at least worth thinking about.

Farming country of the future will be dotted with small manufacturing towns.

Credit Supply's Effect on Business

A new theory of economic cycles, based upon the influence which the supply of commercial credit has upon the volume of business transacted

AN advocate of the science of forecasting business conditions, Clayton A. Penhale, of the Standard Statistics Company, writing in the *New York Tribune*, presents an interesting new aspect of the cycle theory. Cycles must be measured in terms of something or other—in bank clearings or car loadings or basic commodity prices or index numbers of one thing or another, but the author of the new theory regards *credit supply* as the most perfect barometer of business conditions and the stock market.

The theory is based on the idea that the underlying force behind all broad movements in the stock market and business is the supply of available credit. A condition of plentiful credit precedes every upward movement in the stock market and every broad increase in business volume. And credit stringency is the unfailing precursor of every great downward swing in security prices and business activity. Stated another way, prosperity and depression are reflexes of available funds.

The vessel at the left represents the credit reservoir—that is, the banks of the country plus the rediscount facilities of the Federal Reserve Banks.

Fig. 1. This condition has been witnessed, during recent years at the following times: March, 1904; March, 1908; January, 1916; May, 1919, and June, 1921.

At this stage it is time for taking a bullish position on stocks, for with the credit supply plentiful and with business and stocks both liquidated there is only one way for stock prices to go.

On the business side commodity prices are low, with little demand, and trade prospects, on the surface, look black. But sound conditions have been restored by the preceding liquidation, and the first harbinger of recovery in business, the beginning of a rising stock market, is seen.

Fig. 2. This phase of the cycle was witnessed in recent years in September, 1904; December, 1908; September, 1915; July, 1919, and June, 1922.

Stock market conditions at this stage are still bullish. Business is still depressed, but some of the key industries which lie at the base of all business are picking up rapidly. At this stage hardening money rates and the extent of the previous rise in stock prices may entirely mislead the timid investor into selling securities prematurely.

Fig. 3. This phase of the cycle was witnessed in recent years in November, 1905; December, 1909; December, 1916, and November, 1919.

It is at this stage that the time comes for taking a positive bearish position on stocks. This is the typical period of active bull manipulation to distribute stocks. Extra dividends, "melon cuttings" and other devices are used to induce the public to buy. But stock prices have discounted all these.

Fig. 4. This condition obtained in April, 1907; March, 1910; January, 1917, and April, 1920.

At this stage, the bear movement in the stock market actually begins. Business continues to expand on the credit supplied by the liquidation in stocks, but the credit supply is, nevertheless, nearing the point of exhaustion. The strain soon will become acute. It is a period of stiff money rates. This period is marked by forced liquidation in the stock market to supply the funds for continued business expansion. Stock prices, of course, reach a peak and begin to fall as the liquidation proceeds.

Fig. 5

The stock market has been largely liquidated at this stage of the cycle, while business has expanded until its demands for credit have drained the credit reservoir. The inflation has gone as far as it can and the banking situation is so strained that pressure on business is imperative. Consequently it becomes necessary to squeeze the business sponge.

Fig. 6. This phase has been witnessed in December, 1907; June, 1911; November, 1917, and December, 1920.

Loans are reduced to a minimum and this period becomes one of premature bullishness on the stock market. The demand for basic commodities is falling off rapidly. There is decreased output and unemployment results. Along with falling commodity prices, business reaction becomes acute. The banks apply pressure on business to restore the credit supply, with the result that the credit current is reversed, passing from business into the banks. The stock market remains depressed, awaiting the increase in the credit supply.

Fig. 7. This phase has been witnessed in March, 1908; September, 1911; January, 1918, and June, 1921.

This is the time for again taking a positive bullish position on the stock market, for the long pull. Business is still under pressure, but the end of liquidation is in sight. The credit supply has been restored to the normal level and such further liquidation as will take place will refill the reservoir.

Thus the cycle is complete. The question remains, however: "Where do we stand today?" The answer is: "Somewhere between periods 1 and 2." The prospect is that the trend of the stock market will remain upward for some time to come.

When Do Farmers Buy?

THE steady advance in the prices of farm products has brought the great basic purchasing element of our country back into the market again. When it is considered that the farmer represents practically 35% of the "ultimate consumer" population, and that the Department of Agriculture estimates the increased purchasing power due to the rise in farm products to be almost 25%, the importance of this statement will be understood.

According to the *United Business Service*:

"The purchasing ability of the farmer depends on three factors. These are (1) the size of his crops, (2) the price he receives for what he sells, and (3) the price he must pay for what he buys. According to present indications, prospects are that all of these factors will tend to make the farmer's conditions more favorable. The price at which crops will surely be above the levels of the past two years. It must also be remembered that the farmer's producing costs have been somewhat lowered. Labor, equipment and interest costs have been reduced. While it is true that general prices have advanced of late, the rise has occurred chiefly in raw materials and food prices. Since the prices of finished products are slower to advance than raw material, the farmer will continually be benefited by any exchange he makes by selling crops and buying the finished products which he needs. In other words, the rate at which farm prices have been advancing has not been offset by an equal advance in the prices of the commodities he purchases. The exchange leaves him an increasing margin of profit. While the chart of his purchases shows that the farmer does most of his buying in October and December,

the present is none too soon to begin the preparation of plans and campaigns in his behalf. The first essential in selling to the farmer is to get his confidence. The most effective way of getting this confidence is to talk to him in terms of the business of farming. His business is growing things, and being nearer the soil he is more human. Therefore, build sales talk on a foundation of genuine sincerity.

The farmer can be most easily reached through simple human appeals than by a formidable array of facts. A questionnaire recently mailed to the farmer in regard to the kind of advertising he read with most interest placed the newspaper first and circulars second.

We are, however, inclined to favor the direct-mail method of appeal. The farmer is more susceptible to a letter than is a business man. He gets fewer of them. Furthermore they are read in the evening with more undisturbed attention."

Pickling Newspapers

AFTER eight years of experimenting by three big New York newspapers at a cost of \$5000 a year each, the problem of preserving newspapers in public libraries has apparently been solved, according to the American Pulp and Paper Association. Each newspaper sheet is mounted between two sheets of thin Japanese tissues, shutting the air from the original sheet, slightly reducing its legibility, but strengthening the page. Bound volumes of the mounted pages are now in constant use.

Oil from Our Northern Neighbors

As the oil reserves in this country become more limited, new sources of supply must be found—Canada has oil in plenty though little has been utilized.

OIL is one of the world's greatest needs. Sixty per cent of the total supply is now produced in the country, but the United States fields are becoming exhausted, and geologists expect their early decline. When our petroleum is used up where will the bulk of the world's oil come from?

A large part will undoubtedly come from Canada, whose oil fields have enormous potentialities. In western Canada are petroleum territories which have scarcely been tapped, but which, when they are developed, may make our northern neighbor one of the foremost oil-producing countries of the world.

According to latest Government statistics, Canada's annual oil production up to date stops short of 310,000 barrels (90% from the Ontario fields) in comparison with more than 330,000,000 barrels produced by the United States. A leading United States geologist, Dr. J. D. Northrop, recently said, "Petroleum production in the United States is expected to reach its maximum this year and to decline steadily hereafter," while the same authority, speaking about the future of the Canadian resources, continued, "Canada is the only country in which the petroleum industry may be said to be controlled by foreign (United States) interests."

If we take a map of Canada and very roughly draw a line from east of the Great Slave Lake, passing through Lake Athabasca down to the north end of Lake Winnipeg, along the east shore of that lake to its southerly end, thence to and along the north shore of Lake Superior to the Soo, and thence along the northerly shore of the Georgian Bay to Parry Sound, thence due east to the St. Lawrence River, and along the northerly bank of that river to its mouth, we shall have divided the Dominion into two vast areas, that lying to the northward of our line being regarded as generally hopeless for oil prospecting, that lying westward and southward being from its geological formation rich in promise for the finding of productive oil fields within the economical range of practical drilling.

If we further examine the geological map of this latter area, we find that the great oil-bearing strata of the North American continent, which in the United States have been productive of the richest and most prolific oil reservoirs of the world, contributing in fact more than 60% of the world's total oil supply, constitute the principal geological formations and outcrops of this vast Canadian territory.

All of these geological formations in the various oil fields of the United States contribute to the vast total production of the country.

It requires, therefore, no more than an average share of optimism to predict that Canada's future as a world oil producer is certain, and awaits only the assured result of time and capital expended on the scientific location of favorable structures of these formations and their subsequent exploration by the drill.

In the western provinces attention in the past has chiefly been divided be-

tween the possibility of commercial development of the Athabasca River, commonly called the "Tar Sands," and the search for petroleum in the vast regions of the Mackenzie River basin, north and south of Edmonton, in northern, central and southern Alberta, in the Peace River and Great Slave Lake districts, while recently reports are to hand of organization for prospecting and drilling in the districts of Kootenay and Vancouver, B. C.

The outcrop area of the Athabasca "Tar Sands" has been estimated to cover from 750 to 1000 square miles, and the deposits probably extend considerably further to the southward under heavy cover. Various estimates have been made of the probable oil content of these sands, which have been reported to range in thickness from 140 to 225 ft., and to contain 25% of oil, but in fact the numerous shallow wells drilled have only obtained small amounts of black viscous oil showing on analysis a high percentage of light oils. The more volatile and valuable constituents of this petroleum have long since disappeared and, as the flow has ceased, the rocks from which it issued are probably exhausted; in short, these tar deposits are all that remain of a vast oil reservoir now spoiled and wasted. Further, the horizontal stratification of these deposits, according to scientific men, is entirely against the probability that they will in themselves be found to contain reservoirs holding large pools of pay oil, since the entire absence of folding in the strata is unfavorable to the large accumulation of such reservoirs and, moreover, denudation by ancient glacial action has exposed the oil sands to the atmosphere, so that in the course of ages evaporation of the lighter oils has taken place, leaving only the heavy tarry residue, now in evidence, dispersed throughout these vast deposits.

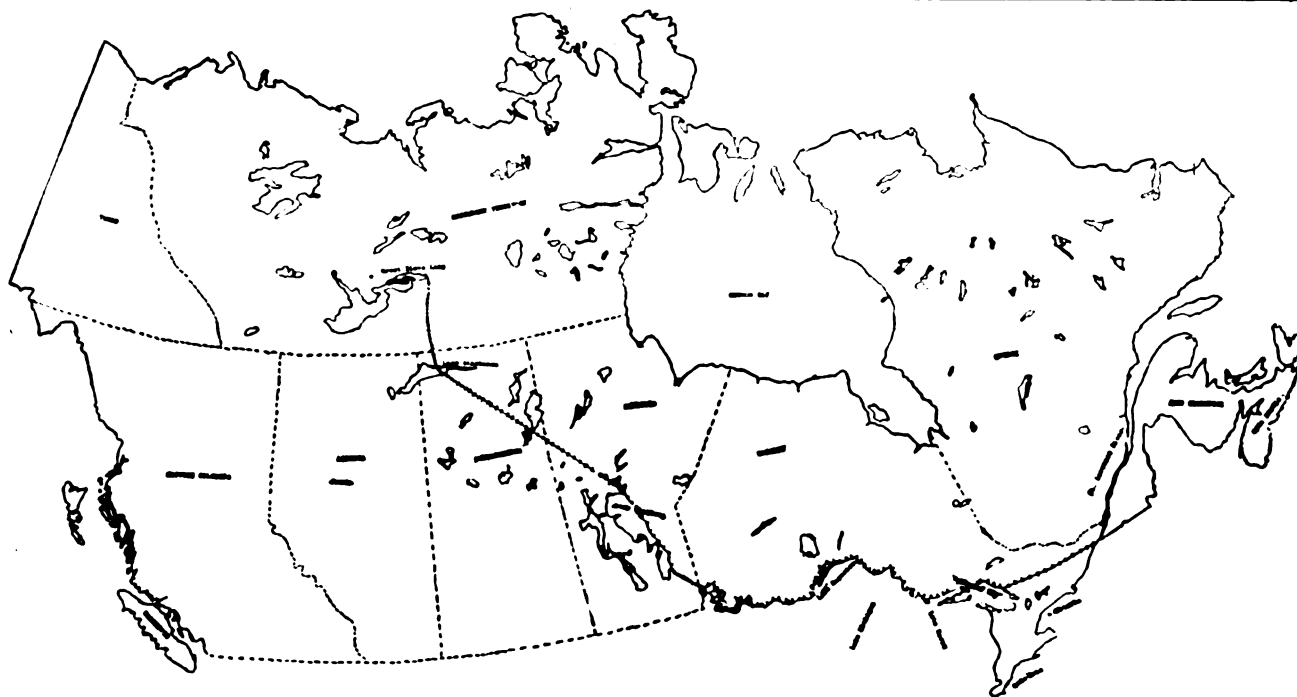

Hence it is likely that for years to come the commercial value of these tar sands will be limited to their development as bituminous road-making material, for which purpose their suitability has already been demonstrated in the city streets of Edmonton, and the economics of the question are being

fully investigated by the Department of Mines of the Dominion of Canada. Improved methods of distillation may make the recovery of the oil content of these deposits a commercial proposition, as also may the future exhaustion of producing oil wells, but this latter is too far in the future to be of interest to the present generation.

In the Athabasca district, at Pelican Rapids, the Canadian Geological Survey sunk a shallow well in 1897, and tapped a heavy flow of gas, and later, at the same place, the Pelican Oil and Gas Company met a heavy gas flow in a shallow drill hole. In 1917-1918 the Imperial Oil Company sunk two wells along the Alberta and Great Waterways railways, and the Tapley Syndicate put down a third in the same territory. These tests were made by practical men, but success was not attained, a small show of tarry oil being obtained at depths of about 1000 feet.

America's most northern oil well, the Pelican, Northern Alberta, Canada.

Outline map of Canada, showing the division of the Dominion into two great areas—that to the north of the line drawn on the map being hopeless for oil prospecting. The area to the west and south of this line is rich in oil promise.

These results do not, however, in any way disprove the presence of pay oil in the vast fields to the south of this area which are so far from the outcrops that even the most expert explorer has little data to guide him, and drilling "in the dark" is the only test that can be resorted to.

The first essential, therefore, for the successful discovery of liquid oil accumulations is the location of suitable structures of the oil-bearing sands, and their exploration by drills, those beds distant from the area of outcrop of the Athabasca sands offering better prospects than those in the immediate vicinity, as also do the regions northwest of Edmonton and Athabasca landing where favorable structures which are independent of these tar sand leakages are known to exist.

The Peace River Oil Company, the Tar Island Oil and Gas Company, the Consolidated Oil Fields, Ltd., the Victory Oil Company, and the Northern Pacific Oil Company have all had drills in this region penetrating to depths of from about 1000 ft. to 1300 ft. Their general experience has been the finding of small quantities of heavy tarry oil, and, in an effort to reach the lower Devonian formations, encountering heavy flow of gas or water which must be shut off before further exploration can proceed. This difficulty is, however, purely physical, and the Three Creeks Oil Company is reported to be now installing large pumping units to deal with this obstacle.

In the district around Calgary considerable drilling has been done, and in some cases small flows of from 15 to 30 barrels a day, ranging from very light to heavy oil, have been obtained. Geological opinion is that in this territory the rapid descent of the oil-bearing strata from the faulted and folded areas created by the mountain uplift has placed these strata at so great a depth in this district as to make drilling a doubtful commercial undertaking. Some experts also hold the opinion that the very light finds of oil in the Calgary field are indications that the original source of the oil, the parent reservoir, was at a great distance, and that the oil in its lateral movement has been subjected to so great filtration as to have rendered it an unpromising prospect. New methods of distillation of these light oils may, however, give them an added value and revolutionize opinion in this respect, converting

this class of oil into a valuable source of supply of motor fuel spirit.

Examination of the vast districts southeast of Edmonton, lying between the North Saskatchewan and the Belly rivers, has determined that the reported anticlinal folds of the upper cretaceous structure do not exist in central Alberta. The homoclinic structure of this area may be responsible for the difficulty hitherto experienced in locating any large accumulations of petroleum oil, but the area is vast and the absence of anticlines does not disprove the existence of such reservoirs.

It is said that the Imperial Oil Company, the Shell Oil Company and some other interests will spend large sums in drilling in this field during the present year, and the activities of such experienced oil men show how great is their confidence in the promise of this region.

The Amalgamated Oil Company, Ltd., and the Crow's Nest Oil Company are reported to have acquired extensive rights in the Kootenay district, and to be either actively engaged in drilling or preparing to do so, and on the international boundary near Vancouver, a company known as the Boundary Bay Oil Company is reported to have drilled to a depth of more than 700 ft. and to have produced a small flow of oil, while in the same district the Pitt Meadow Oil Wells Company and the Empire Oil and Natural Gas Company have sunk wells, and the Spartan Oil Company has drilled a test hole near Burnaby Lake to a depth of about 2000 ft., at a point where one of the most important oil seepages occurs.

In the Vancouver district, oil and gas seepages have been known for some years past, though their origin has not been demonstrated, but it has been thought that they may indicate oil pools in the sedimentary rocks underlying the Fraser River.

This article would be incomplete without reference to the oil fields of eastern Canada, in fact the Devonian formations of Ontario are at present producing the greater part of the output of the Dominion and have been productive since 1857. In this province the Mosa oil field in Middlesex County is the largest producer and contributed 108,988 barrels in 1918

Overequipped In Metal Industries

How much money is wasted every year on account of unnecessary machinery that stands idle much of the time?

ARE America's metal industries vastly overequipped? Are they wasting great sums yearly by carrying more capital invested in plants and equipment than is warranted by the consumption of their products?

That such is the case may be inferred from facts presented by W. R. Ingalls in an address at a recent joint meeting of the Mining and Metallurgical Society of America and the American Institute of Mining and Metallurgical Engineers.

The United States has blast furnace capacity to produce annually 48,000,000 tons of pig iron, Mr. Ingalls pointed out, and the steel works have capacity to produce from pig iron, scrap iron, and pure ores ingot steel variously estimated at 52,500,000 to 55,000,000 tons annually. Compared with this capacity is a maximum pre-war production of 31,000,000 tons of pig iron and 30,000,000 tons of ingot steel.

Copper is a more extreme example. The mines produced ores good for 1,250,000,000 pounds of copper in 1913 and reached 2,000,000,000 pounds in 1916. This figure could be attained only in an emergency and could not be maintained for any length of time. The present mining capacity is estimated at from 1500 to 1800 million pounds per annum, or roughly 1,650,000,000 pounds as a fair average estimate. The copper smelteries, not including those of the Lake Superior region, have a capacity for treating 22½ million tons of ore per annum, yet in the year of maximum production, 1916, they treated only 11¼ million tons. This is overbuilding with a vengeance, especially as the 1921 production was less than one-fourth as large as in 1916.

The product of the smelteries must be refined. The electrolytic copper refineries can handle 2,750,000,000 pounds annually, while other refining processes can handle 250,000,000 pounds. The total refining capacity of the country is thus 3,000,000,000 pounds annually, whereas the amount refined in 1916 (the year of maximum production) from the product of domestic and foreign smelteries was only 1,930,000,000 pounds, decreasing to 1,125,000,000 pounds in 1920 and 921,000,000 pounds in 1921. The amount refined in 1913, the last pre-war year, was 1,225,000,000 pounds.

Much of our copper is exported. The chief domestic uses are in copper wire, copper sheet and brass mills, and can absorb 2,000,000,000 pounds of copper per annum, but before the war their consumption was only 800,000,000 pounds. In this industry of copper we find the smelteries at least 100% overbuilt, as based on maximum war production. They probably are 300% overbuilt as based on normal pre-war production. The refineries are from 50% to 220% overbuilt on the same basis, and the copper wire and sheet and brass mills are 150% overbuilt.

The lead smelteries have a capacity of about 900,000 tons of lead per annum. The maximum pre-war production (1913) was 412,000 tons, the maximum war production (1916) 552,000 tons and the 1920 and 1921 productions 511,000 tons and 401,000 tons, respectively. Some of this overbuilding has a plausible excuse. Certain smelteries have become useless due to the running dry of some mines, with consequent failure of the tributary ore supplies of these smelteries. In the manufacture of blue lead products (sheet, pipe, shot and alloys) there is considerable excess capacity even if capacity is estimated on the basis of one shift per day. This already excessive capacity can be practically doubled in case of necessity.

In zinc there is excess in both mining and smelting capacity

After discarding some of the war plants there is still good producing capacity for 800,000 tons of zinc per year, whereas the maximum pre-war production was 353,000 tons. The 1920 production was 450,000 tons; in 1921 about 180,000 tons.

Excess mine capacity in the coal-mining industry is notorious and has made that industry a permanent source of infection in our economic structure.

The above figures have not taken into account two factors. The first is that an industry must have a certain excess capacity in order to function easily and to meet peak loads. Furthermore, no plant can function continuously at 100% capacity. On the other hand, temporary overloads can be taken care of. Probably 10% excess capacity will be found sufficient in all cases if a wise policy in planning and scheduling production is adopted. The second is that allowance has not been made for natural increase in consumption capacity due to increase in population and other causes. On the other hand, it is to be noted that in certain cases no growth in consumptive capacity is to be expected, for one result of the war is an apparent decrease in consumptive capacity per unit of population to a lower standard than that which existed before the war for many commodities. Population has increased 11% from the middle of 1913 to the middle of 1922. If these two factors of natural increase in consumptive demand due to growth of population and of excess capacity necessary for peak production and as a margin of safety are fully allowed for, we still have in the industries considered an enormous overbuilding.

Waste from Overequipment

THE waste due to this overequipment is obvious. Carrying charges and rapid deterioration of unused equipment cost heavily. The injury to labor and the community is fully considered in the report. There is another serious result of this overbuilding. The industrial processes we use today are the direct descendants of processes used 10, 50, 100 or 1000 years ago. While there have been epoch-making discoveries and inventions, yet advance in technique, lower cost, improvement in product and increased usefulness to mankind have been chiefly by a process of attrition. At one point we have a larger furnace, or a more durable lining, or a more resistant shell, or automatic conveying of materials, or a purer coke, or the recovery of a valuable by-product, or the use of a cheaper ore, or a 5% better recovery of the chief product, etc., etc. These advances in technology are the life of the industry. In an industry which is not overbuilt, obsolete plants are replaced by plants which have embodied in them the best practice of their predecessors, together with some new refinement, some labor-saving device, some method of obtaining a better or larger or more uniform yield.

A heavily overbuilt industry acts as a check on invention and progress. Plants may be run to destruction because it is cheaper to get what is possible out of them than to keep them at maximum efficiency when there is the certainty that they can operate only on part time or at intervals. Now plants are built only when a special reason such as an epoch-making advance in manufacture is discovered or when an exceptionally favorable geographical position with relation to source of raw materials and market presents itself. Obsolete plants are dismantled and not replaced. Improved technique is not adopted. An industry may thus become stagnant and even pass from one country to another where more favorable conditions exist.

WITH THE FINANCIERS

Speculators Raid New York Exchange

PRICES of listed stocks on the New York Stock Exchange wavered uncertainly in the early part of June, and then began to slip downward. On June 12 they executed a sharp and severe dip, and on the very next day recovered.

These antics did not alter the general opinion that we are still in a rising stock market. All shades of sentiment are to be found in Wall Street, of course, but the consensus of opinion is that whatever reactions now take place are merely technical and temporary. Some people who believe in the bull market suspect, nevertheless, that there will be another drop before the steady rise is resumed; but this, of course, is more guesswork. There are others who foresee a general decline in business, accompanied by a drop in speculative securities; but these prophets are very few. Most observers point to the continued optimistic reports from industrial and commercial circles and to the increasing ease in money rates as evidence that further increases in stock prices are due.

The average price of 50 stocks dropped two points on June 12. This was the severest decline recorded since that of June 20, 1920, when the loss was 2.06, according to the *New York Times*. As compared with 81.80, the high record for 1922, the average at the close of trading on June 12 showed a decline of 5.08 points. The drop in stocks was accompanied by a similar break in wheat and cotton, and on the following

day all three markets recovered at the same time.

Wall Street ascribed the break to various causes. Some thought it was due to the fact that Europeans had been heavy speculators in the American markets, and sold their holdings when the news was made public that negotiations for a loan to Germany had failed. Others reasoned that the exposure of the inside deal in the three-company steel merger caused the drop. Still others said it was due to the operations of professional speculators who had tried in vain to drive their favorites up in the preceding days, and who finally decided that the only thing to do was to drive prices down and start again from a new level. The prompt recovery on the day after the break pointed clearly to the operations of professional speculators, who promptly covered their sales at the lower prices.

Bond Market Holds Firm

THE bond market, although somewhat irregular, did not follow the declines in stocks. Trading was dull, but prices were firm. Liberty bonds especially were strong, and high-class corporation issues showed no weakness. Offerings of new issues continued to be lighter than they were earlier in the year.

Callable Bonds Redeemed

CALLABLE bonds are being redeemed in increasingly large quantities. More than \$28,000,000 of these securities

How Commodity Price Fluctuations

The commodities are: cottonseed oil, coke, pig iron, bar iron, pig zinc, mess pork, hides, print cloths, sheetings, and worsted yarns. The prices of these commodities all have similar major fluctuations.

In these charts the logarithmic or ratio scale is used. Consequently, equal percentage changes in each series are represented by equal vertical distances and the differences in the violence of fluctuations of the two curves corresponds exactly

to the differences in percentage changes from minima to maxima in the two series.

The business cycle is clearly revealed over a period of years by the wavelike variations in the industrial, commercial, and financial statistics which ordinarily serve as a basis for judgments concerning the fundamental speculative, business, and banking situation.

were called for redemption during June, the *New York Evening Post* points out. This follows the calling of slightly more than \$26,000,000 in May; and the amount scheduled for redemption in July is said to be substantial.

"The fact that only about \$4,500,000 were called in June of last year is a sufficient commentary on the change in money market conditions which has taken place since that time," says the newspaper. "These facts are full of significance for the investor who still includes among his holdings high coupon rate bonds which contain a clause allowing the issuing corporation the privilege of calling them prior to maturity. There is some division of opinion as to whether money rates will continue to sink during the next few months, but nowhere is the opinion held that any substantial advance in rates is yet in sight. Should rates merely cling to their present levels for a few months longer, it is certain that almost every issue of this character is coupled with a provision allowing the issuing company such an option. Should rates work to lower levels, the investor whose bonds have been called will be faced with the necessity of reinvesting his capital in securities which will give him a considerably reduced income, or else of sacrificing his factor of safety to obtain the yield of his former holdings."

Rail Stocks' Future Excellent

OWNERS of railway securities have been encouraged to expect an increase in the value of their holdings by the month-to-month growth of railway earnings. A railroad official with a reputation for conservative statement estimates that the operating income of the first-class roads for May was about \$60,000,000, compared with slightly more than \$50,000,000 in April.

Basing his judgment on current car loadings, this official estimates that June net operating incomes will total \$65,000,000. On these estimates net income for the first six months of the year will approximate \$333,000,000. The same official predicted earnings of \$755,000,000 for the full year 1922. In

order to earn 5¾% on invested capital the roads would have to show net operating income of \$1,042,032,500.

The Central Pacific Mixup

WHEN the Supreme Court ordered the Southern Pacific to relinquish control of the Central Pacific it started a discussion of considerable proportions. No one now knows just what will happen to the Central Pacific. The Union Pacific Railroad wants the liberated line to be operated independently if it is not permitted to combine with Union Pacific. William Sproule, president of the Southern Pacific system, on the other hand, has pointed out that Central Pacific naturally belongs to his road, and intimated that legislation will be asked overriding the Supreme Court decision.

Fleeing the Public by Radio

THE stock swindler follows the trend of the public interest. Once his most profitable field of operation was oil; now it is radio.

"The radio situation is well on the way to parallel the oil boom, and in the wake of enthusiasm unscrupulous promoters are relieving small investors of their savings," says a statement by Alexander Eiseman, president of the National Radio Chamber of Commerce.

"It is estimated that in the last three months at least 1,250 new corporations have been organized to manufacture radio apparatus. Obviously, all of these cannot have technical skill or requisite standards. In all this mass of ignorance, many must fall. Shoemakers, jewelers, hairdressers, cloak and suit manufacturers, are stampeding into the radio business.

"In addition to the basic engineering and financing problems there are always the manufacturing and marketing problems which must be solved before investments can pay back one penny on principal.

"Investigations have brought out the fact that at least thirty-seven radio apparatus manufacturers at present are infringing upon each others' patents, and at least 1000 other manufacturers are infringing upon patents of several older radio concerns.

Compare With Those of Money Rates

The curve representing commodity prices shows the average wholesale price of ten commodities selected because, first, they are unusually sensitive to price changes and are not greatly affected by the seasons, and, second, they are of a varied nature and are important to the industrial life of the country. The curve representing rates on commercial paper shows the rate on 60-90 day commercial paper in New York. These series reflect very clearly variations in business prosperity, and the

most noticeable feature of the curves is their cyclical movement.

A second noticeable feature of the chart is the correspondence of the major wave movements of the two curves. Comparison of these movements shows, however, that the crests of the waves for interest rates appear to follow, in point of time, the high points for commodity prices.

IN THE MANAGER'S OFFICE

Measuring Management Efficiency

ADDRESSING the *Society of Industrial Engineers*, at its national convention, President J. W. Roe asserted that industrial engineering can best serve industry by formulating a standardized method of measuring the efficiency of management. As a standard of 100% management, the following elements were presented. Perfect management would:

1. Purchase the right materials, of right quality, in the right amounts, the lowest available prices; 2, secure delivery in the shortest practicable time, at the least expense, and always have all material on hand, where, when and in the condition wanted; 3, process 100% of the material through the plant in the least possible time, by the best suited processes, equipment and methods; 4, utilize the full capacity of 100% of the equipment all the time; 5, utilize the full capacity of 100% of the labor hours paid for with the least cost of supervision and general overhead consistent with perfect functioning, and with the least total labor cost, direct and indirect, consistent with sound social and economic conditions; 6, produce goods 100% of which will pass all inspections; 7, keen 100% of all delivery promises, except for causes beyond the control of the management; 8, market 100% of all goods at the least total selling cost, at the best obtainable prices, to customers who pay their bills without delay; 9, would, finally, set up and maintain adequate reserves for depreciation, business depression, provision for growth, etc.

Principles of Management

A MASTER guide for the executive who is studying his organization, whether factory or office, is given in the eight fundamentals of management outlined by H. W. Leffingwell. These principles of management are:

1. *Define your purpose*—you must know *what* is to be done before you can know *how*. This is your master task.
2. *Analyze your problem*—your master task will then break up into many detail tasks. Consider them all—neglect none.
3. *Seek the facts*—study every condition governing each task, find the undesirable elements to be eliminated, the desirable elements to be retained. Then standardize right conditions.
4. *Devise the one best method*—aim to conserve *energy—time—space—material*. Determine relation of details to master task.
5. *Find the person best fitted*—for each task certain personal qualities are essential. In each person certain qualities predominate. Find the person best fitted.
6. *Teach the person best fitted the one best method*—not by driving, but by thorough, patient teaching are understanding and skill developed.
7. *Plan carefully*—right planning of arrangement and sequence of work will enable you to accomplish tasks in *logical order—accurately—quickly—economically*.
8. *Win co-operation*—co-operation means working together. It cannot be demanded. It must be won. Accept your share of the responsibility. Respect the rights and aspirations of others.

Cure for Selling Troubles

THE cure for 90% of selling troubles is in the factory, asserts E. L. Wayman in *Factory*. The product which fills a need at a price which the customer is willing and able to pay very nearly sells itself. To reduce prices to the customers' buying power necessitates the reduction of costs to a minimum. It is a common fault for a concern whose general profits are satisfactory and which manufactures a varied line of products to overlook the fact that it may be losing money on some articles and making relatively high profits on others. Prices based on inaccurate costs tend to encourage business on the unprofitable articles and discourage business on the profitable articles, with the result that average profits are lower than they should be.

A profit and loss statement by lines monthly gives a control

of stock—raw, in process and finished—so that any lack of balance between the three can be detected quickly and rectified. Without a proper balance of inventories, production may be interfered with, large sums of needed capital may be tied up and customers offended by tardy shipments. There is one best proportion for these three kinds of stock and, once determined for a particular business, any deviation indicates that something is wrong.

A feature of the cost system is a departmental analysis sheet which shows each item of overhead expense for the current month, the preceding month, the current period and the same period of the previous year. Taken with the statement of activity of each department as indicated by the productive hours of labor put in, these expense analyses give a close control of the efficiency of each department.

Another step in cost cutting is the study of the arrangement of departments and machines. If a premium or bonus plan is to be put in operation, it is especially vital that equipment should be in the best condition and operations simplified so that standard unit times will be set as low as possible.

Square Peg in Square Hole

HOW to fit the right worker in the right place is explained by Donald E. Rowe in *Industrial Management*. Four major steps are given: (1) determination of the elements to be gone into for each job and the analysis of the various jobs throughout the plant; (2) determination as to just what constitutes the vital elements of the job and the important points to be observed in the type of worker required—such specifications should then be recorded in some usable form; (3) grouping all jobs into classes of a similar worth to the company and establishment of rates of pay for these different classes; (4) assignment of the worker to the proper job and job class. Also the rearrangement, where necessary and practical, of the worker's rate of pay.

In attempting this job analysis information must be secured from two angles: (1) the job or work itself, and (2) the type of worker required for the job. The points to be considered in regard to the job itself are (1) number of people on this type of work at present, segregated as to male and female; (2) previous experience required for work; (3) whether male or female workers are most efficient; (4) age at which worker can start work; (5) time required to learn the job; (6) facts as to whether job is clean, dirty, wet, dry, dusty, etc.; (7) whether work is of a repetitive or varied nature; (8) present rates of pay.

The essential points as to the type of worker desired are: (1) male or female; (2) past experience required; (3) education required; (4) best age to start; (5) length of time required to attain average ability; (6) length of time before becoming efficient; (7) a quick or phlegmatic type of worker required.

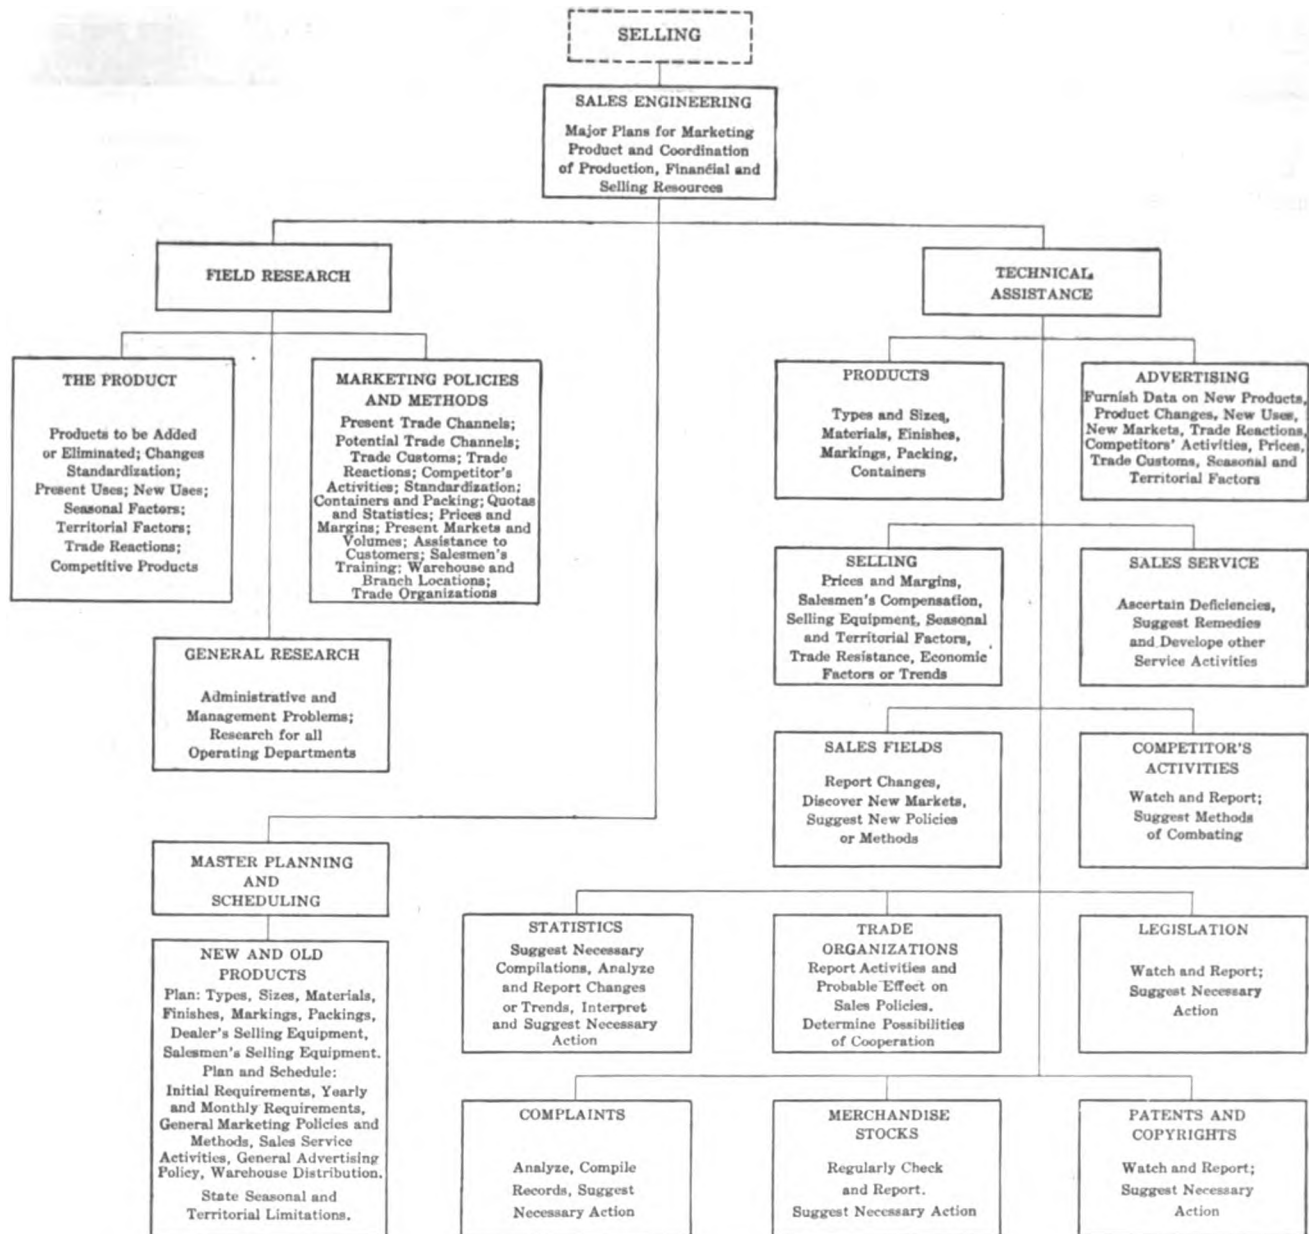

Predetermined Costs

THE advantages of standard costs and the predetermination of costs are recognized in many large industrial concerns, but little has been done to make these advantages available to the medium- and small-sized factory. G. Carter Harrison, writing in *Management Engineering*, offers working plans for standard costs in the first of a series of articles written for the small plant.

A suitable cost system should contain monthly profit and

FUNCTIONAL ORGANIZATION OF A MANUFACTURING PLANT

V SELLING DEPARTMENT (1)

Functions of a Typical Industrial Plant

This chart is fifth in a series based on lectures given at the Bureau of Personnel Administration by Warren D. Bruner.

loss data showing profit and loss realized on the sales for each month analyzed by lines of product, or according to some classification suitable to the character of the business. It should also be possible to obtain prompt and accurate information relative to the cost of manufacturing any standard article under the conditions existing today, that is, current cost data. Predetermined cost data indicating what an article should cost if materials are purchased at certain prices and the factory operated at a certain capacity should be available.

A properly designed cost system does away with the expense of elapsed time clocks and the waste of time of shop operators and clerks expended in furnishing the accounting department with entirely unnecessary information as to the time spent on individual operations.

Data relative to operating efficiencies should be built up on the assumption that the executive is not interested so much in what things are right as in the things which are not going

smoothly. A mere statement of the actual cost of each operation in comparison with the standard cost is of limited value. The information should be so expressed that the executive can see the weak spots in the organization.

A summarized operating efficiency statement, showing actual expenses for the month compared with standard expenses, gives a bird's-eye view of the situation. Items are classified as those beyond the control of the management and those within the control of the management. A saving in cost compared to the standard is shown in black and an increase in red.

The machine rate method is the most accurate system of distributing factory burden or overhead. Under this plan each machine is regarded as a manufacturing unit and is treated as if it were a separate factory, paying rent for the space it occupies and being charged for the use of power and for its share of the indirect expenses of the factory.

A MILLION AND A QUARTER railway employees have had their wages reduced by the sum of \$134,988,919 annually by the orders of the Railway Labor Board. That this cut is unjust and unnecessary and that, therefore, the hearty support of union labor the country over should be accorded the rail unions in their fight to have the reductions removed or lessened was the unanimous opinion of the American Federation of Labor in convention at Cincinnati last week. Prior to the announcement of the third wage cut of \$26,500,000 in the pay of 325,000 rail workers in the clerical and station forces, President Gompers stated that if the wage reductions became effective there would be nothing left for the railway workers to do except to strike. And B. M. Jewell, president of the Railway Employees Department, said: "The railway employees of this country are convinced that certain sinister interests have for some two and one-half years, if not longer, been endeavoring to maneuver railway employees, or at least certain of them, into a position where there might be a hope of crushing those organizations."

The Labor Board, however, maintains that its desire is to be just to all the parties concerned—to establish wages that will be fair to the employees, prove satisfactory to the carriers and impose no unnecessary burdens upon the public.

"In order to get the facts of the railroad wage cut straight," says *The Annalist*, "it is necessary to refer again to the often-quoted elements which the Transportation Act says shall be taken into consideration by the board in determining wage rates. . . . The first one . . . is this: The scale of wages paid for similar kinds of work in other industries."

"It is a curious and interesting fact that the only statistics before the board in regard to wages in other industries were certain very elaborate reports gathered and presented by the railroads, especially those of the Eastern territory (east of the Mississippi and north of the Ohio). The men of the railroad shop crafts are organized in several international unions, which include the workers of each craft both in the railroad shops and in industries outside of the railroads. The International Association of Machinists, to mention one of the strongest and best organized . . . had unrivaled facilities for collecting and presenting to the Labor Board statistics of the rates of wages paid to machinists in outside industries. But it did not present such an array of wage statistics. And this remarkable abstention was duplicated by each of the other highly organized crafts involved in last week's decision."

That no attempt was made to produce figures showing that

outside wages proved the injustice of the wage cut appears to indicate that the actual facts of outside wage rates did not justify the retention of the existing rail rates.

It is pointed out that the Labor Board was governed by the provisions of the Transportation Act, and that uncontradicted wage-rate evidence presented by the railroads appeared to justify the reductions ordered by the board for the shop crafts.

But that the Federation is preparing to resist not only present wage cuts but future wage reductions is indicated by the effort that is being made to add to the ranks of organized labor. Authorization has been given to the three following campaigns: (1) A campaign to unionize workers throughout the country employed in public schools, theatres, apartment and office buildings, such as janitors and elevator men, window washers, etc., into the Building Service International Union. (2) A campaign to organize the 2,000,000 "white collar" or office workers of the United States and Canada. (3) A campaign for complete organization of telephone operators. Other subjects to be considered are: court injunction in labor troubles; opposition to all forms of compulsory arbitration and Industrial Relations Courts, especially the Kansas law; advancement of the co-operative society movement to defeat the high cost of living; unemployment and remedial legislation; affiliation with the International Federation of Trades Unions, representing organized labor of Europe; armament limitations and its effect on labor; old age pensions; legislative attacks on labor. The establishment of a chain of newspapers is also to receive consideration.

Students of the trend of affairs at the convention assert that the policies finally adopted by the Federation may be very different from those adopted in other years. It must be remembered that the most strongly established organizations of wage-earners (the rail unions) have had reductions in their wages, and that resentment over this may drive the union's main organization to a more radical course than it would normally pursue. Although a strong element in the Federation has maintained a conservative policy, a rival element insists that only a sharp and daring change of course can save the union's cause.

But, although the wage reduction is certain to be bitterly protested by labor leaders, a lengthy railroad strike does not seem probable. Not only is the public out of sympathy with strikes, but it feels that in view of the lowered living costs and the need of the railroads for lower operating costs, the wage reduction is a logical step in promoting the

(New Orleans Times-Picayune)
"Coming up at last."

revival of business. The possibility of Government injunctions against a rail strike is also likely to have a restraining influence. Even should the strike be called, it is regarded as almost certain that it would be of short duration.

The Coronado Decision

ALTHOUGH the recent decision in the Coronado coal case has been bitterly denounced by labor leaders as a blow at organized labor, it is the opinion of Ellis Searles, the editor of the organ of the United Mine Workers of America, that this ruling is perhaps the most important and far-reaching court decision ever rendered in a labor case by a court in this country. It is pointed out that under this ruling a labor union now has the same legal right to sue an employer for damages for violation of a working or wage agreement that the employer has to sue a labor union. Also, that a labor union now has the same legal right to obtain an injunction against an employer that the employer has for one against a union. It is asserted that the decision of the Supreme Court in the Coronado case opens the way for labor unions to go into the courts for protection.

"Until the Supreme Court decided the Coronado case," says the editorial, "labor unions did not know they could also sue for damages. But if the Coronado decision is good for one party it must be held good for the other party.

"If a labor union can be sued, as was decided by the United States Supreme Court in the Coronado case, then it can also sue. If a labor union can sue, then there is no good reason why it should not utilize the law and the courts for the protection of itself, its members and their welfare against oppression, damage or outrage.

"The decision says a labor union may be sued for damages to property growing out of a strike. But there are limitations and restrictions to that rule. . . . For instance, the decision says that an international union cannot be held for damages in a local strike that was not called, authorized or ratified by the international. Employers have all along contended that the international was responsible for every act of every member and they have been supported in that position in many courts. . . . A union can now be held for those things for which it is directly responsible, but nothing more. If a strike is conducted along peaceful lines and without violence or lawlessness, as all strikes should be conducted, there will be no grounds for damage suits."

A different view of the matter is taken by Samuel Untermyer. In a recent letter to State Senator Charles C. Lockwood, New York, chairman of the Legislative Investigating Committee, he says that although incorporation would undoubtedly prove helpful to the unions in protecting its members against personal liability, there is another form of regulation which would not interfere with the right to strike or with any other substantial right of the unions—the regulation and supervision of labor unions by a State agency. He believes that labor unions should be required to take out a license and in order to do so its constitution, by-laws, rules, regulations and practices should be subject to the approval of the licensing power. He points out that the practices at which the regulation and supervision would be aimed are in many cases as oppressive against the members of the unions as they are against the public, and that unless the power to eliminate them is lodged in some governmental authority,

organized labor will eventually be driven to its own destruction.

The Amalgamated Convention

"THE convention of the Amalgamated Clothing Workers, which opened in Chicago a week later than that of the International, differed somewhat from the latter in its attitude on amalgamation and political action," says *Labor Age*. But although the convention did not give its support to any political party, it, however, did instruct the Executive Board to make a survey of working-class political parties, report its findings and recommendations to its membership and take a referendum vote if it should discover a political movement representing the ideals of the membership. The next big industrial objective of the Amalgamated, it was decided, would be the establishment of an unemployment fund out of the proceeds of the industry. The officers were instructed to make this question an issue in all future negotiations with employers. An industry must be obligated, the delegates declared, to maintain its workers.

An indication of the thoroughness of the organization of this body of workers is indicated by the approval given by the convention to the establishment of the Amalgamated Trust and Savings Bank of Chicago, with a capital stock—almost completely subscribed—of \$200,000.

Labor's New Platform

DESPITE a hard fight among the delegates to the convention of the American Federation of Labor at Cincinnati, the convention defeated an attempt to force the Federation to go on record for free immigration. The A. F. of L. has consistently supported restricted immigration since 1892, and this year instructed the Executive Council to watch the situation closely and protect American workmen against cheap foreign labor. The convention also went on record opposing the sales tax plan, continuing its efforts to bring about an alliance with agricultural bodies, voting moral and financial support to the striking textile workers in New England, and to striking printers, denouncing employers' organizations as combinations in violation of the Sherman Anti-Trust law. Other resolutions called upon organized labor in every State to start a campaign to have a law similar to Ohio's compensation law adopted in all States, for opposition to the Elkins' bill providing for refunding fines levied upon convicted violators of the Food Control or Lever acts, and the staging of a mass meeting in Newport in support of the strike waged by the Iron, Steel and Tin Workers at the Newport Rolling Mills.

Labor Board Answers Ultimatum

ACCEPTANCE of the \$135,000,000 wage cuts on July 1 will be urged upon railroad workers by the United States Railroad Labor Board in a reply to the "ultimatum" of June 18 from the union chiefs at Cincinnati to the effect that if the workers vote for a strike the leaders will sanction it.

The answer of the board, which is being prepared by Chairman Ben W. Hooper, will go into phases of the readjustment period, such as railroad wages and their relation to transportation costs and to industry and production in general.

(From Trained Men)

EXPORT • IMPORT

WHEN the international bankers' committee adjourned its sessions without agreeing on a loan for Germany, J. P. Morgan, the American representative, announced that the disagreement was largely the result of the attitude taken by France in regard to the reparations. Three plans were presented by the German, Belgium and French representatives. The main points of the French plan were to divide the 132,000,000 gold marks due from Germany into parts, leaving 82,000,000 marks in "C" bonds for the present issue and the remaining 50,000,000 marks in corresponding "A" and "B" bonds in instalments spread over a period of 10 to 12 years. But, according to Mr. Morgan, the placing of even half such a sum, was possible only if France agreed to a reduction in the German debt and repudiation of all idea of recourse to penalties. This the French steadfastly refuse to do; they have, apparently, adopted the non-compromising policy of all or nothing, which makes it impossible for American bankers to assist in floating the loan.

The effect of the rejection of the loan on export trade is twofold. First, a more unfavorable foreign exchange will probably result, and second, there are likely to be fewer purchases of American goods by European buyers. French and Belgian exchange is hardly in the most favorable condition for an increase in exports. Although the English pound has gained 10%, it is still worth less than in normal times. And the extent to which the German mark has fallen has made it impossible to conduct German industry or trade on anything but a speculative basis. It was hoped that the loan would enable Germany to balance her budget and put an end to the reckless printing of paper marks.

High Tariff Adds to Exporters' Troubles

IN addition to the unfavorable rate of exchange, the proposed high tariff adds to the difficulties confronting the exporter. Although Secretary of State Hughes has announced that the tariff is "only a domestic matter," Ambassador Ricci of Italy and Ambassador Geddes of England have strongly objected to this view. All of which indicates the interest taken by European countries in our tariff rates. It is believed that counter tariffs may be imposed by the countries affected and that these restrictions may injure our export trade.

There are, however, several encouraging factors to be taken into consideration. With a steady rise in commodity prices here, manufacturers will more frequently seek export outlets for production, in order to keep prices on the upward trend. After July 1 manufacturers and exporters who enter foreign markets will be aided by a new force of Government trade experts that will be sent throughout the world to develop existing fields.

Foreign trade figures for the month of April show that exports from the United States maintained the same daily average as in March, when they were the largest for any month since October. According to the *American Exporter*, iron, steel, copper and other non-ferrous metals, building materials, cotton, wool, provisions and agricultural commodities are among those which have made advances. During the month of May foreign trade has not only continued the improvement shown in the past few months, but has made further advances. Demands for raw materials and prices have either taken an upward turn or continued a definite upward trend previously started.

April automotive exports showed an increase of 14.7% in value over those of the previous month, further extending the upward curve that started in February. Passenger cars gained 44% in number and 25.8% in value, while motor trucks increased 49% in number and 21% in value. The unit value of passenger cars exported decreased \$107 and that of motor trucks decreased \$263. Parts of cars showed an increase of 9%.

The increase in the volume of exports of crude oil, gasoline and kerosene, which were noted in March, continued during April, the percentage of increase for April over the previous month being 15% for crude petroleum, 10% for gasoline and naphthas, and 14% for kerosene. The movement for the month in these products was substantially greater than for April, 1921, the increase being 23.6% for crude oil, 2% for gasoline and naphthas, and 52% for kerosene. Exports of gas and fuel oil showed a sharp decline of some 20,000,000 gallons under shipments for April a year ago.

A marked increase of Southern yellow pine exports for the month of April, as compared with those of the previous 18 months, indicates a revival of the export trade in lumber.

"At the Pier," a type of attractive illustration found in pages of new German industrial publications.

ADVERTISING

Eliminating Waste in Selling

THE desirability of having salesmen know the cost of each call in order to reduce traveling expense and increase sales is discussed by Roland Cole in *Printers' Ink Monthly* for June. One method whereby a salesman may visualize the importance of planning his work in advance has been adopted by the Lowe Brothers Company. This plan consists in having a large map made of each salesman's territory.

In making the map the names of the State, counties and towns were not placed upon it, but the counties were indicated by letter, A, B, C, etc., the towns by numbers, numbering them according to the order in which they were called on, commencing with the first of the year.

Towns where agencies were located were indicated by a red ring, towns where the salesman still had reason to believe he could land an agency because of work done during the fiscal year were indicated by a green ring; towns where the salesman called and endeavored to establish new business, or where he did not believe there was an opportunity to secure new business, were indicated by an "X" mark. In ink beside each town were indicated the purchases of the dealer-agent in dollars and cents.

Starting on the first day of the year, a string was tied to a nail driven in the location of the salesman's home town. This red string was stretched to a nail driven in the first town made by that salesman; twisted around this nail once, it was carried on to the second town, the third, fourth, fifth and sixth, and back to the salesman's home town, where he spent Sunday. Starting with the next week, a different colored string was tied to the red string at the home point, and his week's travels were indicated by winding this string on the nails driven in the towns which he made that week. This process was repeated week after week with different color string, until the map showed clearly the salesman's travels for the entire year.

In presenting this to the sales force, these strings were wound on the map backward; the last town made in the year was wound on as the first town. This was done to save time, because in showing this map to the sales force a great saving could be made by having the map first strung and then unwinding the strings on the map in the order in which the towns were actually made.

By the side of each town was marked the number of calls made during the year, and below, the total expense of these

calls arrived at by multiplying the number of calls by the cost per call.

Among the points brought out were the following: One agent called on once bought not one dollar's worth of merchandise from the company during the entire year. A town in which no sales were made had been visited seven times at an expense of \$131. One pet account was called on 52 times at a selling expense greatly in excess of the profits made on the account. One so-called agency was called on once, the sales for the year amounting to \$18.20, the cost of the call amounting to \$18.70. An agency buying \$1850 was called on once; another buying \$208 was not called on at all.

By presenting this plan to the men at the annual convention, the danger of making any salesman feel that he was being singled out for criticism was avoided. Nor could the men as a whole feel that the subject was brought forward for consideration as an economy measure for the company. On the other hand, every man looked upon it as an efficiency movement fraught with as much good for the man as for the company, inasmuch as it meant increased earnings and increased business.

Valuation for House-Organ Subscriptions

A NOVEL method of securing interested readers for house-organs is described in *Advertising and Selling*. A value of one dollar was placed on a year's subscription. A cut was made to look like a check with the amount one dollar written in and signed by the company. The "pay to" part was left blank.

These checks were sent out to everybody on the list accompanied by a letter selling the house-organ and offering to send it to those who endorsed and returned the check. Of

course the check carried a line stating it was only good in payment for a year's subscription to the house-organ.

The Slump in Germany

A GENERAL slump in business and economic conditions is noticeable at present in Germany. The production of several of the most important commodities has decreased, and on account of the overpurchasing which has been going on for some time, business is dull in the domestic market. Germany's foreign trade, also, shows the same unfavorable balance which characterized its commerce until December of last year. Industry appears to be hampered chiefly by lack of coal and raw materials and by wage advances.

An automobile advertisement in the German *Illustrirte Zeitung* illustrates not only the use of black and white at which the Germans are adept, but the strong effects that can be secured through simple geometric elements.

AUTOMOTIVE

The Need for Automotive Research

THE increasing importance of research in the automotive industry is emphasized in a special research number issued by *Automotive Industries*. The most important problems covered are those dealing with fuel, highway transportation, aircraft, combustion, engine development, the employment of iron and steel, metals and wood products, and the effect of market research in the passenger-car field, in the sale of motor trucks, and in the development of tractor design.

It is pointed out that the necessity for research in all the departments of the automotive industry at this time is, first, because of the greater demand from the public for more

value per dollar expended. The manufacturer is now faced with the problem of not only giving a better vehicle, if he is to build for the future, but also one at a fair price. The second reason why research is so essential is that the great problem of production which absorbed the activities of manufacturers from 1912 until 1920 is no longer a major consideration. Today the manufacturer is not so much concerned with the problem of how to build more, or in greater numbers, as on how to build better and lower the manufacturing costs as well as the marketing and maintenance cost in every possible way.

Selection of Steels for Automobiles.

Metallurgist tells how important it is to select proper steel, and then to treat it properly so as to bring out the desired qualities. Numerous steel analyses are presented, and the advantages or disadvantages of each are discussed. Importance of ductility is emphasized. W. E. JOMINY, *Automotive Manufacturer*, 4-22, 4000 w. MAH.

How to Select Test and Use Carburizers.

Practical help for men working in carburizing material. Percentage of carbon in the case and rate at which it decreases toward the center, supposedly left soft, are the important points, according to this author, not the depth of penetration. Material specifications are given, rules for selecting the carburizer, causes of soft spots, selection of pots, dependence on the furnace, etc. S. P. ROCKWELL, *Automotive Industries*, 5-4-22, 3300 w. MAH.

Cutting Spur Gears by Hobbing.

Fourth article in a series describing the manufacture of gear by each of the different type of machines which may be employed for this purpose. This takes up hobbing, and is restricted to spur gear hobbing. The mechanical action necessary is described quite thoroughly, then the different machines on the market, the methods of handling the work in and on each. Much other data on gear hobbing. *Machinery*, 5-22, 7600 w. MAH.

Cutting Spur Gears on Gear Shapers.

The third article of a series on the use of different types of gear-cutting machines for cutting various classes of gearing. This deals with machines which operate with a planing or shaping action, and includes the new Stevenson gear shaper which fines a gear complete at one stroke. Interesting details of the machines, their work, work-holding fixtures, including some special and difficult jobs. *Machinery*, 4-22, 5300 w. MAH.

Radial Play in Bearings.

Radial play may be slight and still have large influence on efficiency of bearing. This expert for one of the large bearing companies tells exactly what its influence is, how it is noted and measured, and what measures should be taken to avoid it. T. C. D. CROW, *Motor Trade*, 4-22, 1200 w. MAH.

Milling Eight Transmission Covers at One Time.

Article describes the methods used in one plant making transmission parts. The cluster gear with seven different sizes is cut in one operation, four spur gears are machined in another machine with one set-up, by the use of a large and very special fixture 24 shackle pieces are milled at once, in another fixture used on continuous milling 80 hand-brake levers are finished per

minute, still another permits the production of 40 starter covers per hour, and another allows complete machining (milling) of eight transmission gear case covers at once. The article describes all this equipment, and the methods of using it. J. H. MOORE, *Can. Machinery* 5-4-22, 1950 w. MAH.

Bearing Composition and Renewal.

Bearings are of particular importance, and their composition and renewal equally so. This article describes composition of various kinds of solid, ball, roller and other bearings. Also methods by which they are renewed when worn, or adjusted while in service. Some topics discussed are plain bearing alloys, bearing lining metal, alignment and misalignment, renewal, hot metal may spring shaft, melting out old babbit, heating entire bearing, etc. *Motor Truck*, 4-22, 7100 w. MAH.

Cables or Rods for Brake Couplings.

Many European makers appear to believe that cables are superior to rods for brake operation because of the fact that they use the former by preference. This British author gives examples of practice on the other side in the end fastenings, arrangements to give equal pull, and other details of cable use. M. W. BOURDON, *Automotive Industries*, 5-18-22, 1600 w. MAH.

New Line of Bevel and Internal Truck Axles.

Describes the 1922 lines of truck axles to be produced by the Russel Motor Axle Co. This concern has specialized on the internal gear drive previously, so the production of bevel gear axles is more or less of a departure. These are to be made in three sizes, all for light trucks of $\frac{3}{4}$, 1 and $1\frac{1}{2}$ tons capacity. Details and drawings. *Automotive Industries*, 4-6-22, 700 w. MAH.

Where Our Tires Start.

Contrary to general opinion, rubber is not sap of rubber tree, but is fluid called "latex," found between corky outer part and hard, thin inner tissue incasing the wood. One of best tapping methods is diagonal cut extending third way around tree. Cuts are made with razor-like knife. Cuts carefully made, so they are not too deep, too wide, or not sufficiently deep, in order to obtain maximum quantity of latex. *Motor Trade*, 4-22, 1500 w. BS.

The increasing demand for the light truck is shown in this production chart of trucks by capacities, estimated for 1921.—(*Automotive Industries*.)

Detonation—A Consideration of Its Causes. The tendency of fuels to detonate has puzzled automotive engineers for several years, and this author, in charge of the investigation work of the National Advisory Committee for Aeronautics, describes some of the results of its investigations. The inference is that charge temperatures and pressures before combustion have been considered from the standpoint of their influence upon the temperatures and pressures after combustion, rather than their influence on the rate or nature of the combustion. No definite conclusions are drawn beyond presenting the experiments of the committee and others, especially Harry Ricardo, of England. STANWOOD W. SPARROW, *Automotive Industries*, 5-4-22, 5400 w. MAH.

Motorists pay an average of \$34.67 each in various forms of taxation.—*Tractor World*.

Economics of Motor Transport. Starting with the startling statement that motor trucks are today transporting one-eighth as much tonnage as all the railroads of the country (300,000,000 tons against 2,400,000,000 tons), author outlines entire transport situation. He discusses in order highway efficiency from all standpoints, transport efficiency, and vehicle efficiency. He presents each and every phase of the matter in a fair manner and reaches the conclusion that much additional research is needed, also that motor vehicle manufacturers and users should have a larger voice in the construction of the country's roads, especially those which are national in scope and paid for out of public funds. M. C. HORINE, *Power Wagon*, 5-22, 8100 w. MAH.

Seventeen thousand miles is the average service car owners put their automobiles to in three years.—*Tractor World*.

Truck Overloads and Road-building. Author says "Highway design must necessarily be based upon traffic, and the behavior of the various details of design observed under different ranges and types of traffic; highway transportation is in a state of flux; an immense growth may be anticipated in the next decade." The discussion of the various factors in this situation, such as the character of the major loads and overloads, is based upon the Connecticut census of roads, which was taken in the Spring and Fall of 1921. The most surprising point he makes is that regular trucking concerns are more guilty of overloading than irregular or occasional shippers or truckers. J. G. MCKAY, *Power Wagon*, 5-22, 8400 w. MAH.

Automobiles are replaced with new ones on an average of every five years.—*Tractor World*.

Heavy Trucks and Permanent Roads. Author discusses what is generally understood by a "permanent" road, and what it is actually. Subsequently, he takes up such pertinent topics as foundations, surface materials, proper and improper methods of construction, etc. Next he takes up the problem of taxation to meet increased cost of such road as present-day trucking seems to demand, and concludes that truck owners and users as a class should pay practically all this, despite admitted public

Tractor Production in the United States, 1909-1921, inclusive.—(Automotive Industries.)

benefits to all classes of better highways. E. J. MCCAUSTLAND, *Power Wagon*, 5-22, 3100 w. MAH.

Ten years ago the annual production of automobiles in this country was 181,000; today the capacity is 2,750,000.—*Tractor World*.

Use of Tractor with Grain Drill Assures Better Planting. Argument for the more universal use of tractor indicates that farmer using it may expect better seed distribution, ability to do work at proper time and greater certainty of results. From dealer standpoint, this method should be urged for it means greater sales possibilities. Types of drills for tractor use, two methods of feeding the grain, increased usefulness through use of attachments are among the topics treated. E. R. WIGGINS, *Chilton Tractor*, 5-1-22, 2100 w. MAH.

Only 13,574 manufacturing plants employ over 100 workers.—*Tractor World*.

Notes on Propeller Design. In this instalment the energy losses of the propeller are taken up, and all of them developed mathematically. Essentially an article for the designer and pure technician. MAX M. MUNK, *Aerial Age Weekly*, 5-1-22, 2500 w. MAH.

Eliminating Fires in Airplanes. Author describes special studies of this subject which have been made by the Air Service and shows the progress which has been made in the last year toward fire prevention and fire extermination as well. C. H. BUTMAN, *Aviation*, 5-1-22, 900 w. MAH.

Forest Mapping and Estimating from the Air. A development of aerial photography, showing the application of this kind of work, to the practical everyday needs of a large Canadian lumber company. The area mapped was 140 sq. miles, and the work was done in 12.8 hr. at less cost than the usual timber cruising, which takes months. *Aviation*, 5-8-22, 1100 w. MAH.

Communications and Beacons on Air Routes. Author points out needs for continuous communication with pilots of aircraft, and gives a most desirable method of radiotelegraphy and radiotelephony. Details of the various sets used in both are given. Beacons are dealt with separately, with reference to both day and night beacons. CAPTAIN FRANCK, *Aerial Age Weekly*, 5-1-22, 2400 w. MAH.

Notes on Landing Places for Seaplanes. This deals specifically with the available landing places along the Atlantic Coast, and has been prepared with great care by the National Advisory Committee for Aeronautics. All the landing places in New Jersey, Delaware, Maryland, North and South Carolina and Georgia are described. EWING EASTER, *Aerial Age Weekly*, 5-1-22, 2100 w. MAH.

Principles Governing the Establishment of Meteorological Stations. The subtitle, *Along Air Routes*, taken with the main title, explain exactly what this article describes. The author divides his subject into two parts, distribution and grouping of stations and communications, and develops each topic fully. P. AUJAMES, *Aerial Age Weekly*, 5-1-22, 2150 w. MAH.

BUILDING-CONSTRUCTION

Better Type of Construction Ahead

SPECULATIVE construction has now reached a point where, in many parts of the country, the demand of medium-priced apartments and small houses has been met almost to the point of saturation, points out *Architectural Forum*. This, it is believed, indicates that the crest of the first wave of building activity has been passed and that we are now entering the second and sounder period in which better types of buildings will be constructed. An encouraging feature of this development is that the flow of building materials will be diverted from speculative channels toward the

construction of a great number of educational and institutional buildings, public buildings and business buildings. The present shortage of building materials is expected to be offset by the increased production activity which is to be noted at the plants of many building material manufacturers.

It is predicted that the cost of building will decline gradually, and that the average building project may now be undertaken without fear of a too great decrease in reproduction value with a consequent shrinkage of investment and mortgage loan collateral.

Architectural Acoustics. The first of three articles on the nature and reduction of office noises. Describes methods and results of studies in the noiseproofing of three Federal Reserve Banks. PAUL E. SABINE, *American Architect*, 5-24-22, 3000 w. EMcC.

Building Code Uniformity. Editorial discussion showing that of 15,400 incorporated villages, towns and cities in United States with total population of 54,000,000, and 12,000 "rural communities" with total population of 9,000,000, less than 3% have any building regulations. There are 2800 cities with populations in excess of 2500, of which 1478 have populations in excess of 5000, yet very few under 5000 have any building regulations and only 27% of those having populations in excess of 5000 regulate the character of construction.

Many regulations are of little value and many of the municipalities have no means for enforcing even their inadequate regulations. Proposed regulations for reinforced concrete design prepared by a Joint Committee, consisting of eminent specialists in concrete work are discussed. Two tables show distribution of costs of various parts of concrete buildings in eight cities compared with costs under proposed regulations. Comparisons show reason for differences found in building codes. *Amer. Architect*, 6-7-22, 1500 w. E. McC.

Practical Building Regulations for Concrete Block. Discussion of building code regulations to govern manufacture and use of concrete block, brick and tile, prepared by Portland Cement Association, with ways and means for their enforcement by city authorities. A. J. R. CURTIS, *Concrete Products*, 5-22, 2000 w. CS.

Design and Standardization of Mouldings. Illustrated article covering progress in reducing number of mouldings and standardization. THEODORE F. LAIST, *National Builder*, 6-22, 2000 w. CS.

Concrete Construction. General trend of changes in concrete work has been simplification, but simplification has not come in form of standardization as with structural steel. Doubtful if concrete construction usage will ever become matter of selection and use of standard sections, because of extent of field and of adaptability of concrete to any size or shape. Chief uses are for foundations, concrete piles, substructure walls, retaining walls, floors, slabs, beams, columns, and sidewalls, and or variety of purposes in farm groups. WALTER W. CLIFFORD, *Architectural Forum*, 5-22, 2500 w. HHH.

Prices of Raw Materials and Finished Products Since 1914

The top edge of the black area shows how the wholesale prices of all commodities have varied since 1914. It seems clear now that since the middle of the 1921 we have been on a new price level, slightly more than 50% above that which prevailed before the war. While this is the average condition, it is true that many kinds of goods are a long way above or below this new level. The price, and housefurnishing goods are still higher at 211. On the other hand, metals are 17%, and farm products 26% above the pre-war figures. One interesting circumstance in regard to this unbalancing of prices is that in general the raw materials are principally raw materials—the products of agriculture and of mines—while those represented by the solid line are on which a great deal of work has been done, or the finished product. At the beginning of our participation in the war, the prices of raw materials rose faster than did those of finished products, but with the beginning of the post-war boom, in the middle of 1919, these positions were reversed, and have so remained up to the present time.—(Index.)

Elements of Concrete and Steel Construction. Details of concrete and steel construction, illustrated by diagrams. Essential elements of strength in reinforced concrete lintels, pre-cast tile lintels, cornices, plate girders, lattice girders, fireproofed steel floors and metal lumber floors. *ELWYN E. SEELYE, Pencil Points, 6-22, 1200 w. HHHH.*

Design, Construction and Use of Metal Flumes. Description of semi-circular flumes from standpoint of types, supports, stresses, expansion, end structures and surface coverings, based on Reclamation Service experience. Technical article, illustrated with drawings and diagrams. *JULIAN HINDS, Eng. News-Record, 5-25-22, 7000 w. CS.*

Specifications for Concrete Construction. Continuation of editorial discussion of practical considerations in writing of specifications for concrete construction. Article takes up deposition of concrete in forms and finishing of surfaces. *American Architect, 5-10-22, 2500 w. EMCC.*

Sanitation with Regard to the Sewerage Systems of Buildings. Bacteriologist's views regarding present sewerage systems. Claims present systems not sanitary and cannot be kept sanitary by present methods. Covers formation of and troubles incidental to uric acid scale accumulations. Boiling water will not remove scale. Pipes should be as nearly perpendicular as possible. Poor sanitation provides source of infectious disease. *Bldgs. & Bldg. Management, 5-1-22, 2000 w. CS.*

Important Factors in Building Hollow Walls. As hollow walls become better known they are sure to be more and more popular. Covers insulating and heat-conserving properties of hollow walls and their economy. *LESLIE H. ALLEN, Permanent Builder, 5-22, 1500 w. CS.*

Right Angle Triangulation as Applied to Pipe Fitting. Treatise on pipe-fitting measurement. All pipe-fitting measurements involving triangulation which can ever be taken in actual work, can be reduced and represented by outlines of right angle triangle. Triangulation method simplifies solution of all difficult triangular pipe-fitting measurements and similar problems as well as processes of solutions. Illustrated with diagrams. Part I. *DENIS KEOHANE, Sanitary & Heating Eng., 5-5-22, 3500 w. CS.*

Estimating Cost of Highway Bridges. Two kinds of estimates—preliminary based upon approximate data and should not vary greatly from estimate made from detail plans; and final made after surveys and plans are completed and represent engineer's best judgment regarding reasonable final cost. Dividing estimate into various labor, material and transportation costs is advisable. *WALTER S. TODD, Municipal & County Eng., 5-22, 1200 w. CS.*

Pricing of Roofing. To price by square foot is fundamentally wrong as a cut up roof with battlements, pent houses, skylights and chimney flashings is a roofing job and not a plain roof to be covered. Each job should be estimated for itself and not on a general square footage basis. *Sheet Metal Worker, 5-12-22, 1000 w. APS.*

Building Boom Continues As Costs Decline

Since the latter part of 1921 construction costs have been fairly stable, and with no immediate prospect of their further decline, building activity was further stimulated. The abundance of cheap money was also a factor contributing to the building boom that has swept over the country since last March. Measured by the value of the permits, the amount of building under way at present breaks all previous records. The total value of the permits for the cities enumerated is nearly three times that of the first months of 1914, but part of this increase is due to the increase in the cost of building material and in the wages paid in the principal business trades. The combined index for wages and materials on which the curve of construction costs in the accompanying chart is based is now a little less than twice that of 1914. Meanwhile house rents for the average wage-earner, as computed by the National Industrial Conference Board, have declined slowly from the peak of 71% above the pre-war level, reached in March, 1921, to 65% above that level. — (N. Y. Evening Post.)

Arc Welded Steel Building. By arc welding steel framework savings in time, labor and materials were obtained. Description of method of making joints. The welds passed all tests made by engineers. Five photographs. *B. C. TRACEY, Welding Engineer, 5-22, 800 w. APS.*

Caisson Cofferdam Foundation with Special Bracing. Description of deep cellar substructure in filled ground, caissons braced by built-up struts during excavation, toe wall holding caissons against sliding. Covers: special requirements of filled ground, caisson design, joints, preparing ground, sinking, cofferdam bracing, caisson toe wall, costs. *T. KENNARD THOMSON, Eng. News-Record, 6-1-22, 3500 w. CS.*

Building Costs. Tabulation of costs is given for buildings in a number of States, describing types of construction, equipment, total cost, cost per cubic foot, date of contract. Tenth of series of cost tables, figures for which are furnished by architects of buildings mentioned. *Amer. Architect, 5-24-22, 1000 w. EMCC.*

Standardization in Building Industry. Covers results of work of U. S. Department of Commerce to standardize various building materials and reduce waste. *JOHN M. GRIES, Building Age, 5-22, 1000 w. CS.*

Two-Hinged Timber Arch Used as Temporary Railroad Bridge. Description of structure designed as falsework for erecting 120-ft. girders. Logging railroad traffic now carried by structure. *W. J. H. FOGELSTROM, Eng. News-Record, 5-4-22, 1500 w. CS.*

Design and Construction of Lightweight Floor Systems. Covers practical details of long spans for light loads, comprising core construction, steel joist and precast slab types with special attention to core system. *JACOB FRUCHTBAYM, Eng. News-Record, 5-4-22, 6000 w. CS.*

Structural Design Problems. Second, and final, instalment of article on determination of bending moments, shears, reactions and loads on columns for floors and beams of continuous spans. The methods illustrated are graphical and are given without the use of mathematics. *American Architect, 5-24-22, 2000 w. EMCC.*

Selling Furnace Heating. An address read at meeting of Roofing, Metal and Heating Engineers, containing practical suggestions for arousing enthusiasm in buyers for this method of winter comfort in homes. *M. J. LENIHAN, Sheet Metal Worker, 5-12-22, 750 w. APS.*

CEMENT·STONE·BRICK

Asphalt Consumption Doubled

PERHAPS you thought that the increase in the use of concrete for roadways and the large use of special binding preparations for macadamized roads had cut down the use of asphalt in this country. If so, you will be surprised to learn that the consumption of asphalt in the United States has almost doubled since 1915. The total consumption, including that made from Mexican oils, that made from domestic petroleum, and that known as "native" asphalt, was 2,023,665

tons in 1920, while in 1915 the total was 1,225,447 tons.

In the production of asphalt from domestic petroleum in 1920 California, with nine operators, ranked first; Texas, with four operators, ranked second, and Indiana, with three operators, ranked third, both in quantity and value. These three States reported 82% of the total quantity and 80% of the total value of production in the United States. The outlook for the asphalt business is very promising.

Alumina Cement: Its Development, Use and Manufacture. Gives history and properties of high strength, quick-setting cement now being produced commercially in France. HENRY S. SPACKMAN, *Eng. News-Record*, 5-18-22, 2500 w. CS.

Cement Making in Iowa. Description of three plants and methods used. Covers Gilmore, Pyramid and Western States plants. *Rock Products*, 5-6-22, 3500 w. CS.

Modern Japanese Cement Plant. Concluding article of series. Covers: kilns and coolers, coal mill, clinker storage, clinker grinding, storage and packing, power plant, statistics of Japanese cement. *Rock Products*, 5-6-22, 1200 w. CS.

Properties of Concrete. Results of official tests conducted for controller-general of merchant shipbuilding in England. Results of interest to reinforced concrete engineers whether engaged in ship construction or not. *Concrete Products*, 4-22, 1000 w. CS.

Control of Asphaltic Concrete Mixes. One of the most essential things about operation of asphalt plant is to have adequate and reliable control of all material that enters into mixture. Gives methods used at Minneapolis. ELLIS R. DUTTON, *Municipal & County Engineering*, 4-22, 500 w. CS.

Waterproofing Concrete. Descriptive article, with discussion, on waterproofing of concrete by all known methods. Intended to give specification writers sound foundation on which to base writing of specifications for waterproofing of concrete work in buildings. *Amer. Architect*, 6-7-22, 2500 w. EMCC.

Grading and Measuring Concrete Aggregates. Rigid specifications for concrete aggregates may bring satisfactory results, but concrete likely to be costly. Lack of tolerance more harmful than beneficial. Recommends certain tolerances and gives results of use. R. C. YEOMAN, *Rock Products*, 5-6-22, 1500 w. CS.

Making Concrete Products. Results of research work presented to American Concrete Institute, covering technical production problems and marketing. Covers design and layout of plant with diagrams, curing, designing, heat, boiler, coal, radiation system, marketing. J. W. LOWELL, *Rock Products*, 4-8-22, 4000 w. CS.

First Principles in Quarrying. Covers briefly best methods and necessary equipment. *Stone*, 5-22, 1000 w. CS.

Practical Stone-Cutting and Drafting. Part XX. Covers cylindrical vaulting and domes. Ed. W. HIND, *Stone*, 5-22, 600 w. CS.

Statistics on Stone Production. Gives latest government statistics on granite and marble production. Stone sold in U. S. in 1920 showed increase over 1919 of 20% in quantity and 38% in value. *Monumental News*, 5-22, 500 w. CS.

Importance of Soapstone to Commercial Operations. Most soapstone quarried in Virginia. Covers occurrences, methods of quarrying and principal uses. RAYMOND B. LADOO, *Cement, Mill & Quarry*, 5-5-22, 1500 w. CS.

Selecting and Proportioning Sand Asphalt Paving Mixtures. Sand constitutes from 70% to 80% of coarse

mixtures needed in sheet asphalt paving. Sand should pass 10-mesh sieve, but not more than 5% pass 200-mesh sieve. Gives three-group method of grading, using triaxial diagrams. Triaxial diagrams illustrated and fully described with examples. PREVOST HUBBARD, *Rock Products*, 6-3-22, 4000 w. CS.

Asphalt Paving Inspection. Gives methods and results of asphalt inspection system used in Binghamton, with copy of forms used. W. EARL WELLER, *Highway Engineer and Contractor*, 5-22, 1500 w. CS.

Making Prepared Gypsum Plaster. Description of compact, effective plant making cement and wood fibre, sanded and unsanded. Also markets for sand as separate product in addition to prepared gypsum plaster. *Rock Products*, 5-6-22, 1500 w. CS.

Difference in Solubility and Availability. Part XVI. Covers various forms of phosphates, with deductions concerning capacity of plants to utilize them. GEORGE A. OLSON, *Cement, Mill & Quarry*, 5-20-22, 800 w. CS.

The Lincoln Highway in New Jersey is the most heavily traveled road of its length in the United States, being the main line between New York City and Philadelphia. The 15 miles of non-permanent pavement on this highway cost \$7,918 per mile for maintenance in 1921. The picture shows concrete pavement near Metuchen, N. J.

CEREALS • MILLING

Corn Exports Show Increase

ALTHOUGH the exports of cereals amounted to more than 1,000,000 tons in April, as compared with a pre-war average of 250,000, it is estimated that about half of this amount is made up of corn. For the past six months corn exports have increased, while wheat exports have been steadily declining. The total corn exports for the last four months are more than 850,000,000 bushels, against 38,000,000 bushels for the corresponding period last year and an average of 24,000,000 bushels for the 1910-14 period.

In the opinion of *Modern Miller* this enormous increase in corn exports is in part due to relief corn sent to Russia and in part to large purchases by other countries for direct consumption. It is believed that the relatively low price has been a big factor in this increased demand and that the extensive advertising which corn has had, due to its use in relief work, has been an important factor. It is hoped that a new permanent outlet may be established for the present great surplus in the United States.

Spring Wheat Dockage. Proportion of dockage or weed seed, found in products of spring wheat area, of Northwest has been increasing for several years past. The average dockage for 1903 was 2.2%, for the 6-year period ending 1914 it was 2.9%, while for the 6-year period ending 1920 it was 4%, and for the 1920 crop alone wheat as marketed up to Jan. 1, 1921, stood an average dockage of 5.1%. Cheaper for farmer not to remove dockage. U. S. Dept. of Agriculture finds average amount of foul, or weed seed sown in drills average more than 2%. A plea for better practice and how to cut down percentage. *Price Current-Grain Reporter*, 5-24-22, 1600 w. WRB.

Grain Elevator Construction. Site chosen should be one where main travel can reach elevator with smallest inconvenience. For a country receiving station, elevator that will hold three days' receipts at one time is sufficient. Should have bins enough to hold full carload of each kind or grade of grain received during any one season of year, together with one empty bin for second carload, and another bin to hold wet or heated grain in case of necessity. Equipment should be heavy enough to handle grain as fast as it can be dumped and bins should be self-cleaning. Two most important considerations are foundation of elevator, and power system. In designing elevator, pressure, and variation of loading and unloading stresses must be taken into consideration. *Grain Dealers*, 5-22, 1800 w. HHH.

Automatic Box Car Unloading in Grain Elevators. Description of modern methods for removing grain from box cars, either of the normal type or specially built. These include the power shovel method, the automatic dumper in which the car is tilted so the grain flows out through a special chute inserted in one of the side doors, this being a side tilting method, and the automatic unloader in which endwise tilting only is employed, this method being otherwise the same as side tilting. Cars and unloading apparatus are described in considerable detail. *C. D. Howe, Can. Railway & Marine World*, 4-22, 9600 w. MAH.

A medium size tractor with four-plow bottom can turn 13 acres per day. The old hand plow and two horses could handle 2½ acres—not more.—*Tractor World*.

Grain Elevator Scales. Author's discussions based on 2000 tests of elevator scales, taking up in turn wagon scales, motor truck scales. He gives 11 rules for operating and maintaining automatic scales. Spouting should be direct from scale to car or vice versa. *H. H. ALFREY, Grain Dealers J.*, 5-25-22, 1200 w. WRB.

Science for Bakers. One of series on ingredients used by bakers, this installment treating spices, telling their origins, their outstanding characteristics and their uses. Spices described are allspice, cloves, cinnamon, nutmegs, ginger, turmeric. Under the head of seeds are anise, caraway, coriander. *Bakers Review*, 6-22, 2000 w. WRB.

Development of Baking Industry. (Part IV.) First two parts dealt with bread making prior to use of modern machin-

ery; the third was on bread mixtures. Current part describes development of flour handling equipment, water scales, sifters, batting reels and the economy of proper machinery and kinds and sizes required for various size shops. Illustrated. *Bakers Review*, 6-22, 2500 w. WRB.

Fire Hazards in Bakeries. Baking industry increased 186% during 1914-19 periods, with still greater growth since then. Fire protection methods and devices are discussed, as are various types of ovens, the steps in production of baked goods and special machinery used, with remarks on the product itself. Article of much value to all bakers containing advice on fire prevention. *F. A. CANTWELL, Bakers' Helper*, 6-1-22, 3800 w. WRB.

Value of Good Flour. Sketch of development of milling processes and equipment. Two constituents of flour, from bakers' standpoint—starch, the water absorbent, and gluten, the moisture retainer. Only recently has proper value of gluten been appreciated. Author describes most desirable forms and quality of glutes and other factors that enter into milling good flour. *F. H. BECKER, Bakers Weekly*, 6-3-22, 900 w. WRB.

Bread Weight Standards. Investigation by U. S. Weights and Measures Officials showed that large modern bakery made best showing as to standard weight, 99% showing less than a quarter ounce variation either way. Standardized weights simplify production methods and reduce costs. The following tolerances on the net weight of loaves of bread are recommended: 2 ozs. per pound in excess and 1 oz. per pound in deficiency on individual loaves when up to time bread is declared by the seller to be "stale." Tolerance of 1½ ozs. per pound in excess and ½ oz. per pound in deficiency on the average weight of 10 or more loaves of same nominal weight and same brand or kind, with certain specified exceptions. *Bakers Weekly*, 6-3-22, 2000 w. WRB.

Fire Hazards in Bakeries

(From *Bakers' Helper*)

This table, based on reports by the National Fire Protective Assn. from references by the Underwriters' Bureau of New England, shows the causes of fires in 407 bakeshops.

Cause	Number	Per cent
Ovens	104	25.6
Unknown causes	70	16.0
Ignition of grease.....	52	12.8
Matches—smoking	38	10.6
Heating	24	8.4
Chimneys and flues.....	25	6.1
Lighting	17	4.2
Spontaneous ignition	14	3.4
Rubbish	12	2.9
Miscellaneous	12	2.9
Defective electric wiring...	7	1.7
Exposure	6	1.5
Power	6	1.5
Sparks from chimney	4	1.0
Bread wrapping machines...	3	0.7
Incendiary	3	0.7
	407	100.0

ANALYSIS OF LOSS

	Sprink-	sprink-	Un-	Total	Per cent
	lered	lered	dered		
Loss less \$1,000	85	195	280	68.8	
Loss more \$1,000	6	121	127	31.2

DRUGS CHEMICALS

Number of Fertilizer Plants Increasing

AS a result of the Department of Agriculture's campaign for the fertilization of land, there has been a notable increase in our production of fertilizer. According to a compilation of the Bureau of Census, made especially for the Finance Bureau of the Senate, there are now 600 establishments in the United States engaged in the manufacture of fertilizer. Their combined capital is \$311,633,259 and the value of their products in 1919 was \$281,143,587.

In addition to these plants, there are 598 establishments

engaged in the manufacture of chemicals. The reason for the recent demand for a high tariff protecting American dye and chemical producers will be easily understood when the following figures are taken into consideration: The capital employed by the chemical plants is given as \$484,488,412. A total of \$28,338,749 was paid in Federal taxes and \$3,592,640 in State taxes. Salary and wage payments amounted to \$97,188,958, and the average number of wage-earners employed during the year was 55,586.

Crude Drugs. Analysis of world-wide sources, collection, distribution and quality determination. Some 250 drugs produced within U. S. Majority are gathered in vicinity of western North Carolina. Formerly quality determined by physical appearance. Now chemical and microscopical examinations are used. Today nothing is permitted to be sold as sub-standard quality without its being traced to its last source before release can be obtained from Department of Agriculture. This is in interest of drug trade and cannot but work to advantage of manufacturer. S. B. PENICK, *Drug and Chemical Markets*, 5-17-22, 1000 w. CJW.

Removal of Methane. Method of removing methane from gases to be used in incandescent lamps consists in decomposition of methane into carbon and hydrogen by passage through finely divided nickel at low temperature (about 500°C) with subsequent removal of hydrogen by passage through copper oxide at 500°C. Passage of gas containing 1.5% methane, for example, through nickel at 500°C reduces content to 0.24% and passage through second series lowers it to 0.01%. Advantage in use of nickel rather than copper oxide alone is that lower temperature is possible. Under same conditions of temperature and flow an equal volume of copper oxide gives less than 1/4 decomposition caused by nickel. While mixture of nickel and copper oxide will give equally good results, has disadvantage that charge must be renewed upon exhaustion of copper oxide. Oxidation of exhausted mass leads to oxidation of nickel at as low temperature as 275°C. Nickel oxide in such mixture is not catalytic and mass is no more efficient than copper oxide alone. G. R. FONDA and H. N. VAN AERNEM, *J. Ind. Eng. Chem.*, 6-22, 2250 w. CJW.

Analysis of Palladium. It is shown that mixture of palladium and platinum may be quantitatively separated by dissolving in aqua regia, evaporating to dryness, moistening with hydrochloric acid, adding little distilled water and then a 1% alcoholic solution of dimethylglyoxime, drop by drop, until there is no further precipitation. The yellow precipitate, containing palladium, is filtered off, washed with water and carefully ignited, first in air to drive off organic matter and then in hydrogen to reduce any oxidized palladium to metal. The metallic palladium is then weighed. C. W. DAVIS, *Reports of Investigations, Bureau of Mines*, No. 2351, 2 pp. CJW.

Gelatin and Glues. Present need for standardization in gelatin and glue testing arises from failure of methods to evaluate material correctly, from lack of standard procedures for measuring properties and from absence of scientific method for expressing data which are obtained. Gelatin content of glue or gelatin and also join strength of glue may be correctly indicated by melting point determination. Neither may be assumed to be, in all cases, proportional to jelly consistency or to viscosity at 60° C. Measurement of viscosity of an 18 per cent solution (dry basis) at 35° C. by means of MacMichael viscometer has been shown to be especially well adapted as an indirect estimation of the differentiation of glues and gelatins in order of their melting points and is recommended as basis for primary evaluation of these products. Tests of jelly consistency and viscosity at 60° C. are of value in secondary evaluation, in determining adaptability of given glue to given service. Other special tests are of value but methods should be stated and uniform method of expressing results should be adopted. R. H. BOGUE, *J. Ind. Eng. Chem.*, 5-22, 7500 w. CJW.

Bleaching Powder. Description of plant of Belle Alkali Co., Belle, W. Va. Crushed lime is hydrated with exact quantity of water necessary, the hydrated product screened and delivered by screw conveyors to chlorinating chambers, which are of concrete. Chlorine introduced under slight suction; finished product removed by means of 4 chutes leading from each chamber on longitudinal center line and extending to point immediately above highest point to which container resting on conveyor in working space beneath would reach. Still necessary to spread lime in chambers and to rake finished product and direct it down chute by hand. Specially designed gravity roller system, very heavy to prevent corrosion as much as possible, handles finished product. G. L. MONTGOMERY, *Chem. Met. Eng.*, 5-31-22, 2500 w. CJW.

Stability of Arsphenamine. Arsphenamine (salvarsan) solutions can be kept under nitrogen gas in ice-box for 4 months without noticeable change. At room temperature color changes noted in about 2 weeks, and at end of 8 weeks 10% oxidation has occurred. Thus temperature is very important factor. P. MASUCCI, *Am. J. Pharm.*, 5-22, 1500 w. CJW.

Potash Brines. Process used at Deep Springs Valley, Cal., is described. The deposit is somewhat richer than that of Searles' Lake. Process of separation consists in boiling pot in which temperature of solution is varied and salts are thrown down in order of their solubilities. First step in cooling vats, holding 3000 gal., which are cooled to 10° C. causing separation of sodium sulfate and some sodium carbonate. Liquor then mixed with mother liquor from previous treatment, concentrated in single-effect Swenson "steam basket" type evaporator until test shows proper content of potash and borax. Foaming prevented by addition of slop distillate combined with use of lead plates in contact with steel of evaporator. During concentration all of salt and remaining sulfate separate and settle out. On cooling concentrated liquor potash and borax separate together and are heated with steam, causing borax to dissolve in water it carries, the potash then being centrifuged free of borax solution. L. A. PALMER, *Chem. Met. Eng.*, 5-31-22, 2250 w. CJW.

Arsenic. Ordinary white arsenic largely by-product recovered from flue dust and fume at smelters in Western States. Number of its salts are used medicinally. The disulfide and trisulfide are used as paint pigments. Trioxide used in paints, for preserving hides, as insecticide, etc. M tal used in hardening alloys. Insecticides main source of consumption, being used in lead arsenate, calcium arsenate, Paris green, London purple, and cattle and sheep dips. Considerable tonnage used in manufacture of weed killers. Consumption in 1920 estimated at 15,000 tons. Present price from 7c to 12c per lb. Estimated glass industry uses 2500 to 3000 tons, sheep and cattle dips, 1500 tons; chemicals (dyes, etc.), 500 tons; insecticides, 5000 to 9000 tons. F. Y. ROBERTSON, *Eng. Min. J.-Press*, 5-20-22, 1500 w. CJW.

Sulfuric Acid Fumes. Discussion of importance of fume problem to chemical manufacturer from standpoint of public health, legislation and economical operation. Fume control could accomplish: Betterment of health conditions in neighborhood, elimination of damage to vegetation, elimination of litigation and improvement of production yields. Work of the atmospheric pollution committee of the American Institute of Chemical Engineers is discussed at some length. J. R. WITHROW, *Chem. Met. Eng.*, 5-24-22, 3500 w. CJW.

Ammonia from Sodium Cyanide. Sodium cyanide and cyanate are readily hydrolyzed, giving theoretical yields of ammonia. Iron present caused sodium ferrocyanide formation, starting at beginning of steaming process and reaching maximum at about 475° C., about which it is decomposed. In presence of sodium carbonate little loss of fixed nitrogen. Proper regulation of temperature during steaming process highly important, as is also rate of steam admission. Quantity of steam added must be sufficient not only to hydrolyze cyanide and related compounds, but also to oxidize free iron present; best to use about 50% excess. With 10-in. batch retorts (capacity 300 lbs. briquets) ammonia recovery of 99% and 100% was obtained, while with 16-in. retorts (capacity 640 lbs.) yields as high as 93.7% were obtained. Continuous steamer developed with estimated capacity of 100 to 200 lbs. of briquets per hour, which gave ammonia recovery of 98%. Advantage of process is that no electric power is needed, but main drawback is relatively high cost of cyanide production. F. E. BARTELL, *J. Ind. Eng. Chem.*, 6-22, 8000 w. CJW.

Kelp-Potash. Products of kelp are potash salts, iodine and decolorizing carbons. Other possible materials are ammonia, tar derivatives, creosote and related materials. Most important product is decolorizing carbon, sold as "Kelpchar," which has been successfully applied to a number of industries. Free filtering, affording rapid filtration and clear filtrate. Can be reactivated and used over repeatedly. Potash obtained is of fertilizer grade while iodine can be prepared of any grade desired. J. W. TURRENTINE, *Chem. Age*, 5-22, 1000 w. CJW.

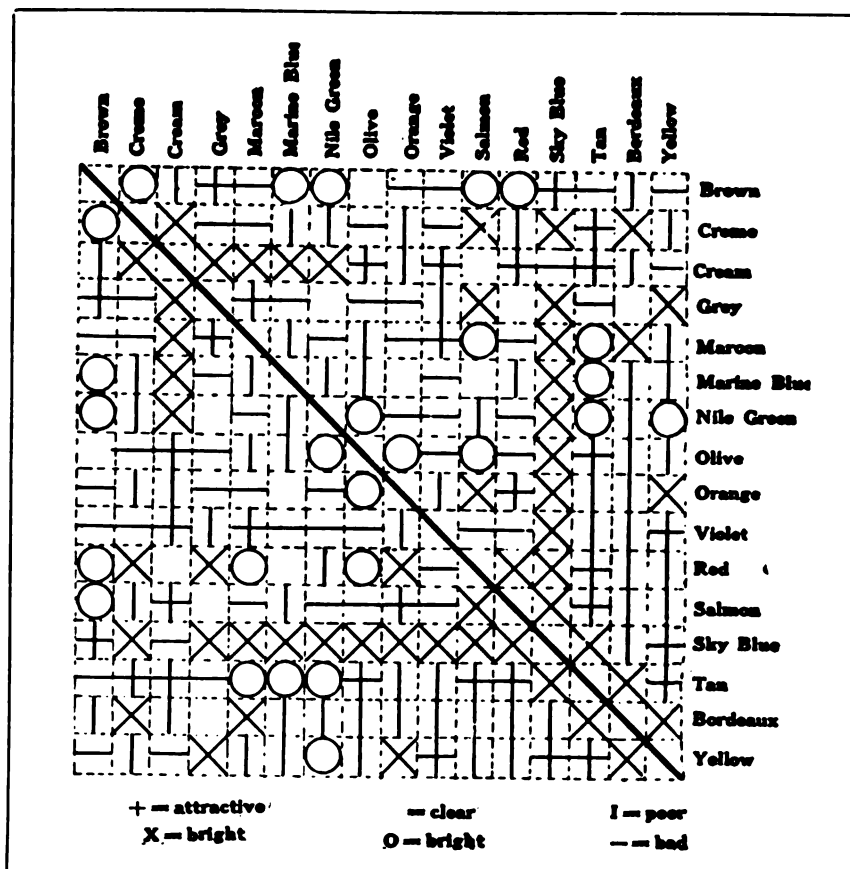

Interesting Sources of Natural Dye-stuffs. Henna is well-known dye plant in Orient. Always been used extensively in India, still employed there for coloring leather and certain fabrics. Use is chiefly confined to tropics. Tutu plant is tropical dye-yielding shrub. Dye is considered superior to logwood, due to purity. Woolen materials take it readily, silk less, and linens still less. Osage orange important dye-yielding plant in the United States, native of southern Arkansas and westward to Oklahoma and Texas, though hardy elsewhere. Yields yellow dye claimed to be superior to fustic. Supply of osage orange said to be limited. Gamboge is important, little-known gum-resins, imported here from Siam. Besides dye, valuable as water-color pigment. Loblolly tree's inner bark was used extensively by early settlers here for dyeing purposes. Lead to almost complete exhaustion of forests. C. D. MELL, *Textile Colorist*, 5-22, 3000 w. MBB.

Color Combination Chart of Interest to Dye Makers

This chart, prepared by *Le Moniteur de la Maille* as a guide for designers of garments, shows effects obtained by combining different colors, value of combination being indicated at point of intersection on chart. For example, grey ground and maroon trimmings make attractive combination, green with red trimmings give very bright effect, while salmon with maroon produces very bad effect. The value of these combinations varies with localities where combinations are seen. In bright seaside sunlight or in the mountains, many diverse combinations are permissible, natural surroundings entering, in a certain measure, into the harmony of the colors.—(*Textiles*.)

Low-Temperature Coal Tar. Detailed study of nitrogen bases, alcohol and sulfur compounds, saturated and unsaturated hydrocarbons found in low temperature coal tar (Carnocool process). Nitrogen bases are 80% tertiary, 20% secondary. Both are unsaturated. No alcohols are present. Hydrogen sulfide is present but carbon disulfide is absent. No single hydrocarbon preponderates in quantity. The non-saturated hydrocarbons belong to same series of cyclic unsaturated hydrocarbons as those occurring in "vacuum tar." Solid aromatic hydrocarbons are absent; liquid aromatics are present only in traces. J. J. MORGAN and R. P. SOULE, *Chem. Met. Eng.*, 5-24-22, 2500 w. CJW.

Dyes Containing the Furnace Cycle. Stable dyes can be obtained from furfural aldehyde and pyromucic acid. In accordance with theory, the furane analog of malchite green has a deeper color than the latter. It is an equally stable dye, giving handsome effects on silk and wool. R. R. RENSCHAW and NELLIE M. NAYLOR, *Textile Colorist*, 5-22, 800 w. MBB.

Fullers' Earth. Fullers' earth highly siliceous clay, usually indurated, with property of absorbing certain organic coloring matters from vegetable and mineral oils. This property can be determined only by experiment. Florida

and Georgia lead in production. Characterized by light weight. Few oils can be used for bleaching both mineral and vegetable oils, but usually limited to one field or another. Description of processes of preparation. Losses in use due to oil film, absorption in pores of earth and in small and inaccessible voids between particles. Technical development in production is next step and will lead to markets otherwise beyond attainment or even conception. T. P. MAYNARD and L. E. MALLORY, *Chem. Met. Eng.*, 6-7-22, 1800 w. CJW.

Pure Ceria Earth Compounds. Procedure depends upon certain solubility relations of sulfates. (See graph.) It amounts to fractional crystallization by heating cold saturated solution to 41° C. until mother liquor is obtained that does not show absorption spectrum of neodymium in thick concentrated layers. Cerium is separated from this mother liquor and pure praseodymium precipitated by oxalic acid in acid solution. Ten fractionations by this process gives product free of praseodymium. Cold saturated solution is now heated to 65° C., and fractionation continued until spectrum of lanthanum ceases to show in mother liquor. From this liquor neodymium is easily obtained. Fractionation of the less soluble part gives lanthanum. R. H. F. MANSKE, *Chem. Met.*, 4-22, 1000 w. CJW.

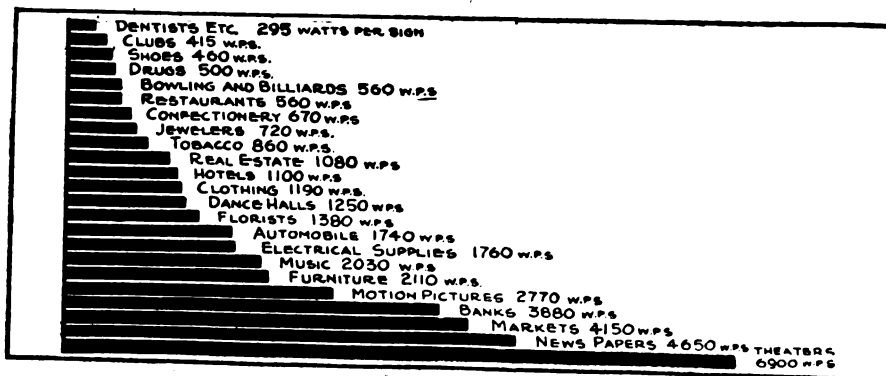

ELECTRICITY

Advertisers' Electric Bill Is Fifteen Million

AN electrical advertising data campaign was recently conducted by *Signs of the Times* with the co-operation of the National Electric Light Association and of the engineering department of the National Lamp Works. Data are available for 40 cities, ranging from a town of 700 people to cities of 300,000, which shows that the average load per display, including all types of signs, bulletin boards, marques, etc., is about 1000 watts.

From the advertiser's standpoint these displays represent a most efficient and effective medium of business promotion,

and from the central-station standpoint they represent a profitable source of revenue. The load burns from 1500 to 2000 hours annually and is constant from day to day. Today the total energy consumption for electrical advertising in this country is at the rate of about \$15,000,000 annually. If the development for all cities were brought up only to the state already obtaining in 10% of them, this revenue would be increased to \$35,000,000 annually. But even in these cities the central stations believe that only a fraction of their market has as yet been developed.

Average load per sign among various users of electrical advertising.—(*Signs of the Times*.)

steel centered cable subject to creeping on the steel center on long spans. In sections where dust storms are frequent sand lodging between wires of the strand caused wearing through of the aluminum wire. *Engineering World*, 5-22, 2000 w. IG.

Electrical Wiring Layouts. In larger residences wiring plans should include local equipment for telephones. Conduits for telephones must be continuous from instrument to instrument and splices should be made in terminal block provided for connections. Conduit from nearest outlet should be run to basement to provide for battery. Where burglar alarm equipment is installed, current is generally derived from battery located in basement or through bell-ringing transformers. System may be closed circuit type, or of open circuit type where contact is closed to sound alarm. Open circuit system preferred for residence work. Wiring should be installed in conduit or armored wire. If desired rubber-covered wire may be drawn into stud constructions. Outlet boxes for all types of equipment should be set at points permitting switches and spring contacts to be mortised in door and window frames or elsewhere. NELSON C. ROSS, *Architectural Forum*, 5-22, 2500 w. (To Be Continued). HHH.

Tests of Storage Batteries for Mine Locomotives. Battery cells at present supplied for mine locomotives have sufficient mechanical endurance to withstand ordinary jolts they are likely to receive in service. Damage to bottom of plates and to inter-cell connector of cells, which became loose in trays, points to advisability of having cells tight in tray to avoid unnecessary movement with resulting wear on cell. Tests show that

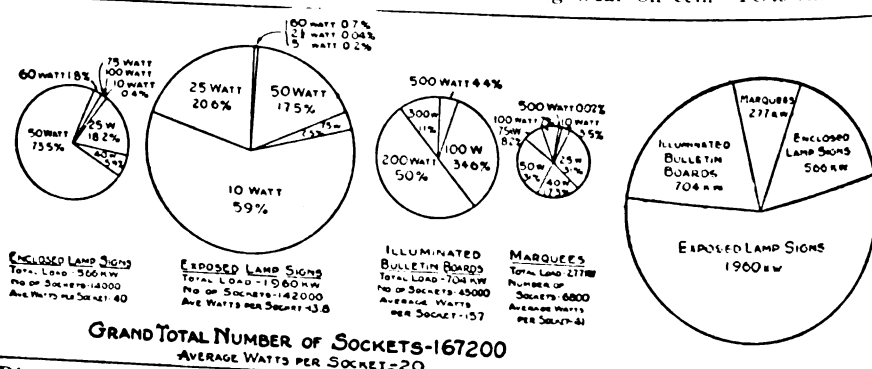

Fifty-Degree Motor. In this motor rise of 50° C. may be obtained when working at full load over continuous working period. Increase in load of this motor beyond that which it is rated will cause breakdown of insulation; 40° motor has safety factor of 10°. Practically all arguments of 50° advocates are defensive. They arouse suspicion of potential purchasers because of altruistic sound. More frankness on part of manufacturers would be fairer to market. Reduced first cost of 50° motors makes their application more advantageous than that of 40° motors in few limited cases, three cases being given. Few coal mines to which 50° motor can be satisfactorily applied as 50° motor. Only in some cases of centrifugal pump drive would this seem satisfactory. In second class mentioned motor limited to heavy flywheel drives, such as tiple machinery. These motors should then be selected of sufficiently increased capacity so that they will operate at normal load with 40° temperature characteristics. This often means overmotoring and increase in first cost. E. D. KNIGHT, *Coal Industry*, 4-22, 3500 w. CJW.

Electric Motors for Grain Elevators. The reduction of danger from fire in the use of electricity as the driving force makes it particularly attractive in grain elevator operation. The different classes of motors which can be used for this purpose are discussed. The question of enclosing the motors is discussed likewise. Switches, fuses and connections are also gone into. H. E. JOHNSON, *Grain-Dealers J.*, 2500-w. IG.

Central Station Power in Coal Mines.

Efficient public service has made central station electricity big power supply for coal mines. Various uses of electricity named. Only most favorable private plant of relatively large size could deliver power at same price as central station power. Cost, reliability and service important factors. One important phase of purchase of this power is study rates. Central station should be interested in success and prosperity of its consumers and should be an ally in production which is an advantage in no way offset by private plant. C. J. DAMON, *Coal Trade Bulletin*, 5-16-22, 2000 w. CJW.

Copper in High-Voltage Transmission Lines. Comparison of relative merits of copper and aluminum in high voltage transmission lines shows copper to be the more advantageous of the two. Mechanical factors in favor of copper. Aluminum does not withstand corrosive action of sea air. Aluminum on large

Distribution of sign load according to type of display and watts per socket in electrical advertising.—(*Signs of the Times*.)

Every electric outlet may soon be not only a source of light, heat, power, and time, but entertainment and instruction as well. Right now it is possible to furnish through one socket or one outlet, simultaneously, all of the different services from any number of separate outlets on the same circuit, at the user's convenience.--
(*Electrical Merchandising.*)

no great hazard will result from use of properly installed and cared-for batteries in permissible locomotives. L. C. ILSLEY and H. B. BRUNOT, Bureau of Mines, Reports of Investigations, No. 2358. CJW.

Electrical Phenomena by Metal Deposits. Every mineral body which possesses electrical conductivity for a sufficient vertical distance and which is encased in earth in such fashion that some of its parts are above ground-water level, produces, in surrounding wet rocks, electrical currents which are detectable. Maximum value does not exceed few hundredths of volt with difficultly oxidizable ores and may reach volt in anthracite schists. Action may extend 200-300 meters from great pyritic masses. Theoretical explanation given. C. and M. SCHLUMBERGER, *Eng. Min. J. Press*, 5-20-22, 750 w. CJW.

Caisson with Water-Ballast Tanks Lays Submerged Floor. Description of caisson and method of laying submerged floor at hydro-electric station. JAMES A. BJERREGAARD, *Eng. News-Record*, 5-18-22, 500 w. CS.

Geography of Electrochemistry. Two main applications of electric current in chemistry are source of heat and powerful decomposing agent. Factors in cost of electric heat as compared with combustion heat. Conditions in various countries discussed. Struggle for supremacy is going to be between U. S., Norway, India, China, and Canada. U. S. far in lead now, but rapidly growing manufacturing industries will gradually attract cheap power now available to chemical industry, for they are better able to pay higher price. W. S. LANDIS, *J. Ind. Eng. Chem.*, 6-22, 2500 w. CJW.

Temperature Regulator. Toluene-mercury regulator is placed so bulb dips into water bath. Ton transformer (used for running toy electric trains, etc.) is adjusted to 10 volts, connected with regulator and relay in such way that 110- or 220-volt current through relay will heat electric immersion heater or operate solenoid water valve by which cold water supply from cooler may be either

released or withheld. PAUL S. PITTENGER, *Am. Pharm. Assoc. J.*, 5-22, 2500 w. CJW.

Variable Voltage Elevator Control. Perfecting of variable voltage elevator control affords a system which offers many advantages over commonly used rheostat control. New system consists primarily of traction elevator motor connected electrically to a direct current generator. Control is obtained by varying field strength of generator. Various apparatus used is described. Lower power consumption, saving of time in starting and stopping, etc. are mentioned among the advantages of the new system. W. H. PATTERSON, *Building and Building Management*, 5-15-22, 1G.

Low Voltage in Mine. Not only does this mean annoyance and impeded operation, but also that more machine and locomotive armatures are burned out when voltage is low and that it involves

continuous loss in money. Counter-electromotive force alone saves motor from acting as short-circuit. Where weak power is furnished energy is wasted, for motors run at low efficiency and work is spent in forcing current through line. Efficiency figures are worked out. E. D. KNIGHT, *Coal Age*, 5-18-22, 1600 w. CJW.

Electricity in the House. Fifth in series, dealing with the bedroom. There is a cut of a well-arranged and well-wired bedroom. M. O. WHITTON, *American Architect*, 5-10-22. EMCC.

Radiophone and Automobile. Description of the more compact forms of radio apparatus which are applicable to the ordinary car, and method of adapting the radio for this use. It is pointed out that it would serve well in calling for help when in distress, would help in operating the car, and as a means of pleasure at the end of the day. Various suitable antennae are described. *Automobilist*, 5-22, 2800 w. MAH.

Applying Electricity Scientifically to Factory Problems. The article describes what can be done by adapting electricity to special needs of a factory by an example showing how special conditions in a Hawaiian sugar mill were met by carefully designed machinery and accurately planned layout of the wiring, etc. L. F. LEUREY, *J. of Electricity and Western Industry*, 5-1-22, 4500 w. IG.

Making Filament for Electric Light Bulbs

This machine draws tungsten wire into the fragile filament used in electric light bulbs, and does the work expeditiously and accurately.—(Photo by Galloway.)

FUEL POWER

Gas Industry on Upgrade

ACCORDING to the *Gas Age-Record*, there has been a 25% increase in the demand for manufactured gas during the last two years. Of the total income from city gas plants (as distinguished from by-product coke plants) almost \$280,000,000 of the total \$300,000,000 came from the sale of gas; only slightly more than 6% of the total value of gas and by-products is represented by the value of the by-products.

The efficiency of the gas plants is evidenced by the fact that the unaccounted for gas has decreased very much in the two-year period from 1918 to 1920. Because of reorganized company system and increased post-war efficiency only 8.2% was unaccounted for in 1920. This latest figure represents the best average performance the industry has ever attained.

In many other particulars the efficiency of the industry showed marked improvement in 1920. The yield of coal gas in thousands per ton was 3% greater during this year than two years before, and simultaneously with this increase in gas yield there was a 2.7% increase in coke yield. Water-gas plants showed corresponding improvement of operating results, since 10% less solid fuel, in pounds per thousand cubic feet, was required in 1920 than two years before. There was also a decrease in the oil consumed equal to an average of 0.2 gallon per thousand made.

The figures for 1920 show that the gas industry as a whole for that year was decidedly upgrade and it is predicted that the upward trend will continue during the coming decade.

Froth Flotation Tests on Bituminous Coal. Tests on bony coking coal (Wilkeson mine) have shown that cleanest coal can be floated first, bony coal next and ash last by ordinary froth flotation. Very thin oils or soluble frothing agents work best. Fine sizes of coal float most easily and coal in very fine slime will float to some extent without use of any flotation oil whatever. Due to tendency of fine sizes to float so easily, they are practically "overoiled" and produce dirty concentrate when enough oil is added to float coarser sizes. To take due advantage of above facts it is necessary to use flow sheet in which roughing treatment is followed by cleaning of both concentrate and tailings from roughing cell, discarding as tailing material which will not float in any of re-treating cells. Re-treatment of middling with original feed is not desirable except for middling obtained in cleaning rough concentrate. By this method clean concentrate can be obtained, bony portions of coal forms middling which may have market value and tailing is too low in coal to be of any value. Attempts to control flotation tests by sink-and-float tests with heavy solutions have failed on fine sizes of coal due to their supposed porosity. O. C. RALSTON and G. YAMADA, *Chem. Met. Eng.*, 6-7-22, 4000 w. CJW.

Coal Amalgam. Discussion of Trent process. With fine grinding almost all but inherent ash is removed. When wet, pulverized coal, suspended in water, is treated with about 30-40% as much oil as there is coal substance, it agglomerates into pasty, plastic mass in which all coal ingredients and oils are intimately mixed. Ash content reduced to practically one per cent. Treat both coal of low-ash content and low grade fuels such as lignite and anthracite culm, containing 30-40% ash. Crude and cheap oil as efficient as higher grades. Greater quantity and better quality of distillates can be made from amalgam than from same materials separately. G. H. DACY, *Coal Age*, 6-8-22, 1500 w. CJW.

Water Returns to Steam Boilers. If pipe connects steam space of boiler with point where return connection is usually made, in effect this pipe becomes part of boiler same as adding section to sectional boiler. Return connections can be attached to this pipe at height correspond-

ing to safe working water level in boiler and thereby secure same result as would be obtained by delivery of water directly to boiler at water line although it is actually introduced at usual bottom connection. Has other advantages. *J. Am. Soc. Heating Ventilating Eng.*, 4-22, 1200 w. CJW.

Fuel Economy. Air washing makes use of process capable of removing from air large proportion of dust, bacteria and solid particles. Recirculation provides plentiful supply of air with no apparent sacrifice of wholesome properties. Fuel economy, figuring 70% recirculation, is calculated to be 52%. Problems pointed out. N. A. HOLLISTER, *J. Am. Soc. Heating Ventilating Eng.*, 4-22, 2000 w. CJW.

Coal Gas Manufacture. Processes in horizontal, inclined and vertical retorts. Vertical not widely used in America has many advantages. Extent and importance of coal gas industry. Reasons for former ascendancy of water gas and the present trend toward increasing use of coal gas. Necessity for a regular by-product market. The role of coal gas in conservation of natural resources. J. J.

MORGAN, *Forging & Heat Treating*, 5-22, 3500 w. APS

Gas Generator Operation. Triangular charts are used to indicate the processes that take place in the generation of gas in the gas producer. Three periods in the operation of the generator are described—drying, distillation period and gasification periods. Methods of regulation are developed from the data given on these charts. A. W. H. GRIEPE, *Amer. Gas J.*, 5-13-22, 6000 w. IG.

Gas-Fired Hot Water Systems. Gas installation shows saving of \$62.75 per month in installation using 75,000 gallons per month. Comparison is made between different installations. A. A. SCHUEZ, *J. Am. Soc. Heating Ventilating*, 4-22, 1200 w. CJW.

Low Temperatures. Popular brief account of liquid gases and their behavior under various conditions. R. F. YATES, *Tyco's; Power House*, 6-5-22, 1500 w. CJW.

Determination of Aromatic Hydrocarbons. New method of determining the benzol content in technical gases is based on absorptive powers of charcoal. Details of method are given. Comparison with other methods in common use indicated that the new method gave higher results, which were the more accurate, as the older ways did not absorb all the benzol in the gas, this being especially true when the percentage of the hydrocarbon in the gas was small. E. BERL, K. ANDRESS and W. MUELLER, *Amer. Gas J.*, 5-13-22, 1800 w. IG.

Fallacies of Heating. Heat alone, without changing air, cannot drive out or absorb moisture; it can only convert it into vapor, which remains where it was generated until carried away by current air. Gives application to drying out plaster. HENRY ADAMS, *National Builder*, 6-22, 1000 w. CS.

Handling of Natural Gasoline. The use of this new product in refining and producing motor fuel is discussed in detail. The method of opening the cars, gauging of the gasoline, sampling, unloading, pumping into cars, etc., are described. The precautions that must be taken are told. D. E. BUCHANAN, *The Oil Weekly*, 4-15-22, 5000 w. IG.

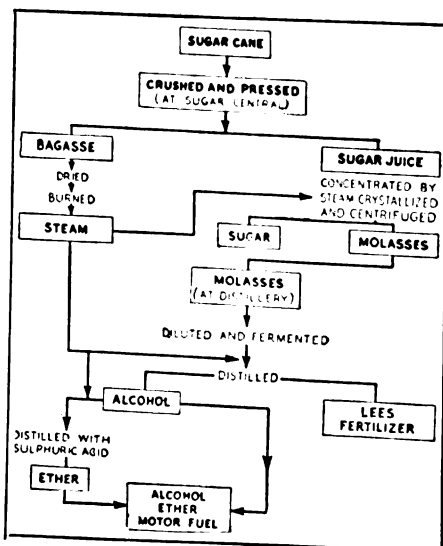

Diagram of the process of manufacture of alcohol-ether motor fuel from by-products of the sugar industry, prepared by D. H. I. Cole and published in *Automotive Industries*.

Mechanism of Coal Carbonization. Decomposition of coal substance to ordinary high-temperature tar when subjected to action of heat is process of progressive, step-by-step decomposition, in which pyrogenetic syntheses play only secondary part. Six-membered rings and combinations thereof characterize entire series of decomposition products from coal to high-temperature tar. Average molecular weight of liquid intermediate products constantly decrease as temperature of carbonization rises. This decrease is marked by evolution of hydrogen, methane, and ethane. Initial decomposition of low-temperature tar first formed is brought about by loss of hydrogen from portion of the naphthenes with resultant increase in proportion of unsaturated hydrocarbons; loss of sidechains from phenols by hydrogenation with resultant formation of lower-boiling phenols; and loss of hydrogen from nitrogen bases to form large proportion of tertiary compounds. (This stage represents Carbocoal tar.) Final decompositions are at maximum between 700° and 800° and are marked by dehydrogenation and dealkylation of hydroaromatic unsaturated hydrocarbons and nitrogen bases to form aromatics, with elimination of hydrogen, methane and other simple gases; hydrogenation of phenols to aromatic hydrocarbons and of these aromatic hydrocarbons to lower boiling aromatics, with formation of methane, ethane, and water; and secondary pyrogenetic syntheses of higher aromatics from simple compounds. The phenols of low temperature tar are the principal source of monocyclic aromatic hydrocarbons. The unsaturated naphthenes of low-temperature tar are principal source of polycyclic aromatic hydrocarbons. J. J. MORGAN and R. F. SOULE, *Chem. Met. Eng.*, 5-31-22, 4500 w. CJW.

Low Temperature Carbonization. Range of temperature lies between 550 and 800° C., all coals being amenable to efficient treatment within such limits. Critical stage from 700 to 800° C., when great care has to be exercised in heating so as to prevent exposure of distillate to these temperatures. This limitation is characteristic limitation of low temperature system of carbonization and has probably prevented commercial success of some proposed schemes. Discussion of best fuel for low temperature carbonization, difficulties of low temperature intumescence. Essential to combine rapid low heating and conservation of by-products. Key to problem in equilibration of these opposing factors. By presenting heat on one side of charge and passing heat there through transversely, simultaneously withdrawing distillate under suction, possible to affect any desired temperature drop across charge thickness by variation of thickness and temperature and heating control at flues. By placing zones of heating flues along height of retort and operating each stage or zone under separate heating conditions, readily possible to treat traveling charge in steps and thereby effectively realize possibilities of each phase of process. These principles claimed to be embodied in Davies system of low temperature carbonization. W. E. DAVIES, *Gas Age-Record*, 5-13-22, 2500 w. CJW.

Power Drills. Where car supply is adequate and men can load steadily, power drills increase output. Where

How Coal Is Wasted in Electric Power Generation.—(Gas Age-Record.)

coal is unusually hard good practice to use portable motor-generator set or motor-driven compressor. Their use gives greater energy and drilling speed is increased. Various types of drills illustrated by cuts. N. G. ALFORD *Coal Age*, 5-18-22, 1200 w. CJW.

Boiler Water. Four major factors affect priming. Relative importance are: Change of load, 70; load, 15; concentration, 10; height of water in glass, 5. With boiler water concentration at 30, load not in excess of 180% rating, with water level under half glass and boiler pressures held within 5 lbs. variation in 10-min. intervals, fairly dry steam may be obtained. Most serious trouble is blocking of feed lines. At least once a year, entire feed line must be removed and turbed out. Boiler scale must be

Combustion Engines. General discussion of operations of starting up, shutting down and routine running of combustion engines. Should be of interest to people with little knowledge of engine operations. *Power Plant Engineering*, 5-15-22, 1400 w. CJW.

Economy of Damper Regulations. Explains use and value of automatically controlling rate of combustion in steam boilers by means of damper regulators. W. F. SCHAPHORST, *Sanitary & Heating Eng.*, 5-5-22, 1000 w. CS.

Savings about Furnaces. Suggestions for rapid and enduring furnace renewals. Radiating from furnace walls should be prevented. Because of shrinkage and inability to bond tightly, fireclay has been displaced to great extent by cements. Good cement will not fuse within range of temperature of boiler furnace. Various cements listed by manufacturers. Tight baffles are indispensable for attainment of maximum efficiency with watertube boilers. More heat can be abstracted from gases, as they move through various boiler passes to flue. Main purpose to cause heated gases to sweep over maximum area of tube surface. Monolithic baffle walls composed of cement, cast in forms, are advantageous. Walls in bad condition may be improved by plastering interior with firebrick substitutes. Most of air that leaks into boiler through walls, not being under control, lowers temperature of flue gases without in any way aiding in combustion. A. F. BROSKY, *Coal Age*, 5-18-22, 2000 w. CJW.

Power Costs in Mining. Power costs at Kathleen Mine (Dowell, Ill.) are analyzed and costs of individual processes given. Reasonably steady run reduces cost of power by nearly half, figures varying from 6.43 to 13.36 cents per ton. Haulage is greatest power consuming process. Ventilating load is remarkably constant. Metering of mine makes it possible to ascertain where power purchased goes, necessary preliminary step that must be taken if power leaks are to be stopped. E. MCAULIFFE, *Coal Age*, 5-18-22, 1500 w. CJW.

Electrical Gate Valves. General discussion of power operated valves and of Dean valve in particular. Dean system of valve control has six particular features: Single unit system, can be attached to existing valves with a minimum of effort and without shutting down line; positive in operation and does not depend upon momentum or drift of moving parts to seat; has ample seating and unseating torque; whole unit is enclosed and waterproof and gas tight; applicable to 220 volts 25, 40 or 60 cycle single phase alternating current, also 110 or 220 volts direct current. Control of valve is by means of one standard control station for one or more points. 16 suggested gas industry applications are given. C. E. REESE, *Gas Age-Record*, 5-20-22, 2000 w. CJW.

IRON • STEEL

Electric Furnace Steel from Pacific Coast

STEEL products "made in California" may some time lead the world, says a writer in the *Journal of Electricity and Western Industry*. Due to the superabundance of hydro-electric energy, the entire Pacific Coast offers great possibilities to the steel industry of the future. Perhaps the most important effect of the use of the electric furnace will be that of building up the iron and steel industry on a quality basis. For, although this furnace cannot compete on a strict tonnage basis with either the cupola or open hearth, its superiority is evident when the question of quality comes into play.

Just what quality production will mean to the steel industry may be realized when the reason for the extensive use of Swedish iron is taken into consideration. Because of its

reputation for excellence as being the base of all Sheffield tool steels, Swedish iron has been preferred by manufacturers of fine products. But today there are shops in this country making products as fine as the Sheffield tools from iron which has been refined in the electric furnace and from which phosphorus and sulphur have been eliminated to the same degree as in the best Swedish iron.

As a result of the development of electric steel, steel castings, iron castings, high-grade forging ingots, alloy steels, special iron castings for electrical and heat-resistant use, corrosion-proof castings, etc., can be successfully produced at a cost that will enable the American manufacturer to meet foreign competition.

Melting Cast Iron. Discussion of Booth rotating electric furnace, including refractories, electrodes, power, rotation, charging, slagging, temperature control, pouring and metal losses. Analyses are given which show effect of melting on chemical composition. Comparative physical tests are given of heats of cast iron made from borings, pig and back scrap, and all back scrap. Effect of steel and alloy additions on the physical properties are shown in tests of several typical heats. H. M. WILLIAMS and T. B. TERRY, *Trans. Am. Electrochem. Soc.*, 1922, 10 pp. CJW.

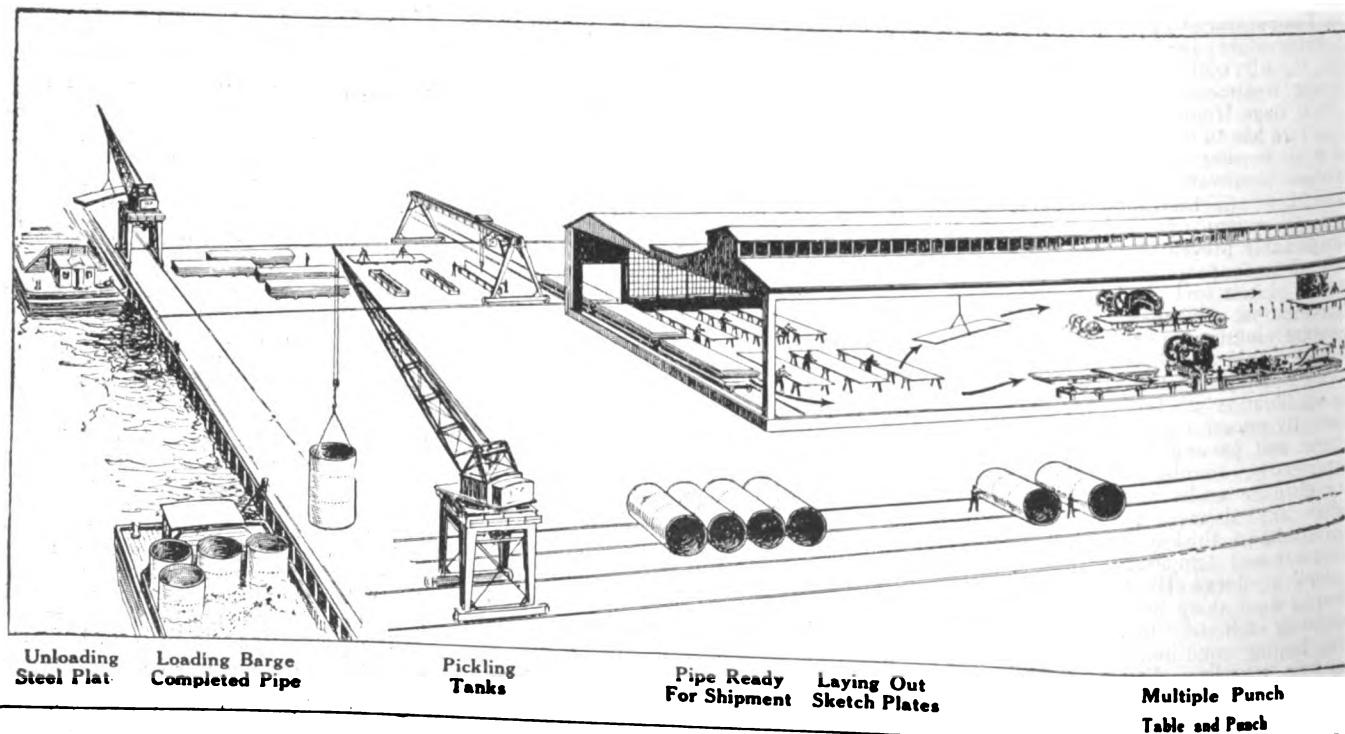

Synthetic Cast Iron. Scant literature of electric furnace cast iron is reviewed,

showing that duplexing process probably first was used on commercial scale in foundry in Cincinnati, O. Conditions favorable to electric furnace for cast iron are discussed and preference expressed for duplex process with basic-hearth electric furnace. Desulfurization and deoxidization in electric furnace are described. Problems involving sulfur, oxygen and other gases and impurities—all brought up by electric furnace practice—are discussed and several lines of investigations suggested. G. K. ELLIOTT, *Trans. Am. Electrochem. Soc.*, 1922, 13 pp. CJW.

Cast Iron from the Electric Furnace. History of electric iron. The possibili-

ties of this process especially in refining the metal; desulfurization and deoxidation. The outstanding advantage of the electric furnace is the fluidity of the charge, which means solid castings. GEORGE K. ELLIOTT, *Iron Age*, 5-4-22, 2500 w. APS.

Synthetic and Electric Iron. Low phosphorus pig-iron scrap steel is synthetic pig iron, from ores is electric iron. Expects electric furnace to become adjunct of the foundry and to use steel turnings as raw material. Open-top and shaft furnaces have been used. Discusses possibilities of economically manufacturing electric iron from ores. ROBERT TURNBULL, *Iron Age*, 5-4-22. APS.

The adoption of the facilities and equipment of a shipyard for general engineering purposes affords a striking illustration of the part shipyard machinery now plays in industrial progress. With the employment of modern machinery and the use of up-to-date methods, progressive industrial management holds

A Comprehensive View of the Layout for the Fabrication of Large the secret of efficient and low-cost production. The story of the fabrication of large-diameter riveted steel pipe for use in the Catskill Aqueduct, for the Board of Water Supply of New York City, demonstrates how this combination is being efficiently effected. The accompanying illustrations portray the

Corrosion of Iron. Danger in corrosion of holder plates by electrolysis, due to impurities in iron, is increased, due to fact that they are alternately wet and dry. Correction is possible only before holder is built, that is, pure iron must be used. Initial rust film formed on commercially pure iron is uniformly tight and close adhering, thereby retarding corrosion and eliminating pitting danger. D. M. STRICKLAND, *Gas Age Record*, 5-20-22, 1000 w. CJW.

Heating and Cooling Steel. Brings out facts that uniformly heated steel requires more than a uniformly heated furnace and a "good" pyrometer record; that human element is very important and that care must be taken to insure proper thermal expansion and contraction by proper loading at low temperature and slow firing. JOHN A. SUCCOR, *Amer. Soc. for Steel Treating*, 5-22, 2500 w. APS.

Abrasive Qualities of Steels. Tests made on machine which is diagrammed and described. Low carbon plain steel and chrome nickel low and medium carbon steels were tested in the form of rollers after heat treatment. The greater the density and hardness, the greater the abrasive resistance. Tension and Brinell tests are not reliable index to abrasive qualities. Carbon steels showed more uniform results and less wear loss than chrome-nickel steels. A. M. COX, *Amer. Soc. for Steel Treating*, 5-22, 4000 w. 12 Figs. APS.

Impact Testing Methods and Results. Impact testing machines are of numerous types. Only four, Fremont, Charpy, Izod and Stanton, are reviewed. Specifications of test specimens and arrangement of testing machines. Numerous

tables, figures and photographs of impact fractures on various types of steel. Concludes that impact test is very sensitive and shows up characteristics of steels not brought out by other mechanical tests. JOHN M. LESSELLS, *Amer. Soc. for Steel Treating*, 5-22, 7000 w., 22 Figs. APS.

Heat Treatment and Magnetic Properties of Steel. Measured intensity of magnetization and coercive force. Saturation intensity is unaffected by heat treatment, but coercive force declines as hardening strains are removed and more so as grain growth commences. LANCELOT W. WILD, *Amer. Soc. for Steel Treating*, 5-22, 4000 w. APS.

Acid Open Hearth Process for Gun Steel and Fine Steel. Part 3 of detailed description, covering prevention of transverse cracks, octagonal and square molds, hot top and discard, top and bottom pouring. W. P. BARBA and HENRY M. HOWE, *Blast Furnace & Steel Plant*, 5-22, 2500 w. APS.

Tropenas Converter for Steel. A blowing process, but more suitable for small heats than bessemer process. The cupola charge. Details of working the converter. Acid lining so low phosphorus and sulfur charge must be used. Details for converter. S. R. ROBINSON, *Blast Furnace & Steel Plant*, 5-22, 2200 w. APS.

Effect of Quality of Steel on Case-Carburizing Results. Usual assumption that chemical specifications are sufficient for steel to be used for case carburizing is not borne out by facts. Structure of case before and after quenching is affected by actual condition of steel itself as made. Excess of dissolved oxides in steel as made in melting furnace affects

permanently the results obtained in carburizing and hardening. 23 figures. H. W. McQUAID and E. H. EHN, *Forging & Heat Treating*, 5-22, 3000 w. APS.

Heat Treating Costs. Interest, taxes, depreciation and repairs, land and building charge, equipment, indirect labor, supplies, power and fuel, general factory burden, miscellaneous charges; form of labor ticket, non-productive labor ticket, lost time and allowance ticket, etc. HAROLD F. WOOD, *Amer. Soc. for Steel Treating*, 5-22, 4000 w. APS.

Methods Used in Specialized Production of Cast-Iron Pistons. In the manufacture of cast-iron pistons in large quantities, the machine tools are fairly simple, and to a certain extent standard. There is, however, opportunity for the exercise of much ingenuity in working out equipment, fixtures, jigs, etc., which will permit of cutting down idle time, increasing the output, permitting the use of cheaper labor, or otherwise helping to cut down costs. This author describes the methods of the Foster Machine Co. with a light-weight piston which is a large seller for replacements. Both foundry and machine shop equipment is mentioned and illustrated. J. EDWARD SCHIPPER, *Automotive Industries*, 4-27-22, 1700 w. MAH.

Diameter Steel Pipe for Use in the Catskill Aqueduct, New York

various stages of fabrication. Ten thousand tons of steel enter into the fabrication of this riveted steel pipe line, which, when laid down, will extend six and one-half miles from Cold Spring to the Harlem River tunnel, near Pleasantville, N. Y. The diameter of the pipe varies from 7¼ feet to 8½ feet in diameter

and is made in 22½-foot sections. The process of the fabrication of the pipe line is perhaps the most modern in the records of general engineering methods, and has attracted the attention of engineers in foreign countries as well as construction engineers of all kinds in the United States.—(Chester Compass.)

MINING

Economy in Copper Production

ANOTHER example of the elimination of waste in industry is furnished in the recent production of copper sheeting from leach solution at one of the large copper plants in the Southwest. As a result of this close cooperation between mining and manufacturing processes important savings are effected in time, overhead, labor and transportation charges.

For the purpose of producing the sheeting, a revolving drum is employed somewhat similar in appearance to an Oliver filter, the bottom of which dips in the high copper solution from the leaching vats. Cord is wound spirally on

the surface of this drum, after which the surface is coated with a solution of sodium sulfide. Current is then applied from an electrode in the bath and travels through the solution to the surface of the revolving drum on which copper is deposited. This is wound off on spools, washed, passed through machines and pressed into shapes, which are afterward soldered together to form radiators for automobiles. *The Engineering and Mining Journal* points out that a number of other all-copper articles might successfully be made in a similar manner.

New Nickel-Copper Deposits. This deposit has been discovered near Shebandowan Lake, Canada. Essentially pyrites, contains nickel as polydymite and copper as chalcopyrite, while the platinum group was present at rate of 0.16 oz. per ton. Considerable exploration work will have to be carried on before commercial possibilities are known. J. G. CROSS, *Canadian Mining Jour.*, 5-5-22, 1500 w. CJW.

Globe-Miami District, Arizona. General discussion of this district, with data on its geology and the various copper-mining companies in operation. The district furnishes 10% of copper mined in U. S., and 6% of that of world. Possible life of district is at least 15 years and probably much longer. Some silver and gold also mined. *Arizona Mining Jour.*, 5-1-22, 88 pages. CJW.

Gold in Canada. Prophecies about gold production in Canada are injudicious. Increased capacity is planned at Porcupine. Conviction prevails that widespread distribution of gold throughout northern Ontario will afford enough meritorious properties to broaden movement throughout district. Cheap hydro-electric power is indispensable to those who would hasten development. Custom smelters needed. Elbow Lake now in limelight. Other promising districts. A. GRAY, *Eng. Min. J.-Press*, 4-8-22, 1500 w. CJW.

Cost of Milling and Treating Ores. Tables of itemized costs are given, together with results of operations of

individual plants. Calculated in value of metal extracted rather than in assays of mill feed. Breaking, 7 to 13 cents per ton of mill feed. Secondary crushing, 10 to 20 cents. Grinding, 10 to 20 cents, to give product of which 15% to 50% passes a 200-mesh screen. Sliming, 15 to 50 cents, reduces a feed all of which passes a 10- to 20-mesh screen and gives product of which 90% 200-mesh screen. Cost of crushing to slime, for each percentage of product that will pass 200-mesh screen, per ton of run-of-mine ore, $\frac{3}{4}$ to 1.5 cents. *Eng. Min. J.-Press*, 5-27-22, 2000 w. CJW.

Strip-Pit Economics. Stine Coal Co., Bear Run, Pa., is stripping large area (about 250 acres at present completed) of coal, thus making it ready to be loaded and shipped when market conditions warrant. Stripping is safe means of storing coal ready for quick shipment. "Carrying charge" comparatively small and risk from spontaneous combustion slight. Greatest depth of overburden is 40 ft., and average is 20-25 ft., of which 10 ft. is shale and 10 ft. thinly laminated sandstone, covered with clay and alluvium; 340-ton shovel, with 80 ft. boom and 6 cu. yd. dipper, used for stripping. Coal loaded out with smaller shovels. Water problem also important. Boiler feed pipe lines are leveled with transit to avoid trouble from frost. Haulage and shooting methods are discussed. A. F. BROSKY, *Coal Age*, 5-11-22, 2500 w. CJW.

Miners' Safety Lamp. Three general methods used for testing for gas in

mines: Use of normal flame, use of short or immediate flame about length of normal lighting flame, and by use of "cap" flame, blue in color. "Cap" flame detects presence of more than 1% of gas under all ordinary conditions. Special precautions to be used in connection with safety lamps are: Lamp to be locked before entering mine; examine carefully, even if passed by inspector; carry no key or other unlocking device; use great care in assembling lamp; lamps must be opened only at regular lamp stations; do not set lamp on bottom of mine; use no lamp with dirt or oil on gauze; do not allow flame to smoke. Other precautions in Miner Circular 12, Bureau of Mines. *Coal Trade Bul.*, 5-1-22, 1500 w. CJW.

Singing Safety. Germans have perfected lamp to serve as warning for miners already provided with electric lamp, but who cannot determine with it character of air in which they are enveloped. Signal is audible and therefore more likely to be heeded. Based on principle that flame burning in interior of glass tube under certain conditions will give sound audible to ear. First sound when air contains 2% of methane; loudness will increase till percentage of methane is 4; with more than 5% or 6% of methane flame will go out. A. GRADENWITZ, *Coal Age*, 5-4-22, 400 w. CJW.

Flame Safety Lamp. General discussion of gauze requirements for safety lamps, and tests which showed that for high temperature, steel proved superior to either brass or copper, though at low temperature the advantage is small. Single gauze bonneted lamp is safer than either type of unbbonneted lamp. omission of a gauze being more than offset by bonnet. Double gauze bonneted lamp safest. Description of two most important lamps, Koehler and Wolf. R. Z. VIRGIN, *Coal Trade Bul.*, 5-16-22, 2000 w. CJW.

Progress in Mining Machinery. Two general types of coal-mining machines are: puncher and chain cutter. Of chain cutters there are three types: breast, continuous undercutter, either longwall or short wall, and center cutter, including top cutter. Three others used somewhat are Hess dustless machine, Jeffrey heading machine and Oldroyd machine. Operation of these types described and illustrated. Power requirements shown

Methane gas caps, showing relative sizes. See "Miners' Safety Lamp" digest.

by means of curves. Attitude of unions opposed to adoption of modern machinery. *Coal Age*, 5-18-22, 3500 w. CJW.

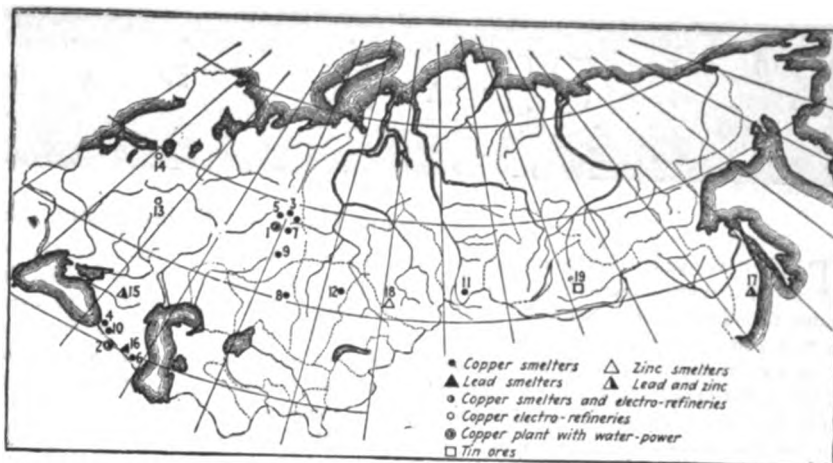

Shoveling Machines. Discussion of various types of shovels and their application to coal industry. Factors militating against their use are difficulties with labor and lack of sufficient and efficient superintendence. Machine having large capacity must have continuous supply of cars. First large cost and idle time are arguments against large shovels. Loaders that are not shovels but mere loaders which themselves have to be loaded, but, being loaded, will raise coal, transfer it and drop it into car, seem to have reason for being which their lower speed of operation and imperfect service would seem to deny them. They are more flexible and can be used where roof is not particularly good and coal is thin. Handling of cars should be carefully planned so that tracklaying, timbering, etc., is not done by loading crew. *Coal Age*, 5-18-22, 4000 w. CJW.

Katathermometer. Preliminary study, in connection with mine dust and ventilation investigation indicates that instrument will probably be useful for making routine determinations of comfort conditions in mines and that it may also prove useful as important accessory for investigative work on problems in ventilation and kindred subjects in both coal and metal mines. Instrument measures its own rate of cooling when its temperature approximates that of human body and thus serves as index of rate of cooling of body itself, which is said to be controlling factor in determining comfort or discomfort. *Bureau of Mines*, Investigation No. 2355. CJW.

Mine Locomotives. Tension of trolley should be noted, socket kept lubricated and tension spring adjusted as necessary. Recommended pressure of controller fingers should be maintained as closely as possible. Should be lubricated with vaseline but not used in excess. Arc barriers should be cleaned to maintain insulation necessary. Wood of drum should be kept clean and periodically resurfaced with shellac or non-conducting paint. Frequent inspection desirable. H. H. JOHNSON, *Coal Age*, 6-8-22, 1200 w. CJW.

Mechanical Loading in Metal Mines. Need of some sort of standardization apparent but progress has not reached stage sufficiently advanced to require more than very general standards. Two sets of conditions where results expected are radically different: Where speed is first requisite with costs secondary and where cost per ton receives first consideration. Results of questionnaires to representative mining companies discussed. Greatest differences reported were in sizes of cars serving loaders and in gauge of tracks. Standard sizes of pipe-fittings and connections, bolts, etc., have been secured to some extent. Certain standards of personnel, such as size of crews, also need attention. L. EATON, *Arizona Mining Jour.*, 6-1-22, 1000 w. CJW.

Incline Slicing Method. Description of method as adopted in mines of Morenci, Ariz., district. Tons per man increased over figures obtained by flat slicing system (from 5.4 to 8.8) and costs show decrease of 15% in favor of incline

Location of copper, lead, zinc, and tin smelters of Russia, arranged according to metals smelted, and size.—(Eng. & Mining J. Press.)

1. Karabash smelter (Kyshtim district). Dressed ores. Water power. Own cheap coal. High-priced custom cokes. Efficient labor.
2. Alla-Verdi smelter. (Bangerur district). Dressed ores. Water power. Expensive cokes. Oil fuel cheap. Persian labor of low efficiency.
3. Bogoslovsky smelter. (Bogoslovsky district). Undressed ores. High-priced cokes. Cheap coal. Good labor.
4. Dzansoulsky smelter. (Batum district). Dressed ores. Expensive cokes. Oil fuel. Labor not efficient.
5. Vylsky smelter. (Vylsky district). Undressed ores. Expensive cokes. Peat and wood fuel. Efficient labor.
6. Kodabeg smelter. (Elizavetpolsky district). Undressed ores. Oil fuel. Expensive cokes. Inefficient labor.
7. Kalatinsky smelter. (Verkhl-Isetsky district). Being enlarged.
8. Spassky smelter. (Spassky district). Flotation plant. Being enlarged.

9. Tanalyksky smelter. Small production. Capital lacking. Copper ores contain high gold content.
10. Kvarzhana smelter. (Batum district). Under construction.
11. Kalselaky smelter. (Minusinsky district). Undressed malachite ores. Cheap wood fuel and charcoal.
12. Pavlodarsky smelter. (Pavlodarsky district). Shut down.
13. Electrolytic refinery of Moscow (formerly Vogan). Custom high-grade copper. Oil and peat fuel.
14. Electrolytic refinery of Rosenkrans. (Petrograd). Custom high-grade copper. Imported coal. Oil fuel.
15. Alagir smelter. (Zinc and lead).
16. Alikent smelter. (Lead only). Inactive.
17. Ore dressing plant only. Lead and zinc ores of the Primorsky district.
18. Ekibastus zinc and smelter. (Kiddersky district). Under construction.
19. Tin ores of Onon.

method of stopping. Timber consumption slightly higher (9 as compared with 7.9 board ft. per ton). Method shown in three diagrams. J. P. HODGSON and J. KIDDER, *Eng. Min. J.-Press*, 5-27-22, 1000 w. CJW.

Refinery Practice in Smelting Cyanide Precipitate. Practice at Buckhorn, Nev. The filter cake, briquetted with litharge and suitable fluxes (soda ash, borax glass) smelted in small blast furnaces with coke and old slag. The resulting bullion is cupelled. Flue losses were found to be small as were fume losses in cupellation. E. R. RICHARDS, *Eng. & Min. Jour.-Press*, 5-20-22, 1700 w. APS.

Heap Leaching of Low-Grade Copper Ores. This process economical in double sense: cost of treatment and recovery extremely low, and method is applicable to ores too low in copper for ordinary smelting or milling. First used in Spain and for 20 years in Australia. Lately introduced in Bisbee district. Ore crushed to 10 mesh and assaying 2% copper, using solution containing 2% iron, gave, by percolation only, an extraction of 50% in 58 days. Various experimental results reported. Large scale test, with 300,000 tons of ore, now under way. Process needs control, leaching solutions should be distributed carefully, so that washing and percolation are always under control. Treatment of heap will continue for 3 to 5 years, depending on various conditions, chemical and mechanical. As a rule, profitable extraction should be complete within 5 years. (To be concluded.) *Eng. & Mining J. Press*, 4-29-22, 4500 w. CJW.

Slope Accidents. More men are killed and injured by haulage ropes on slopes than any other way in same portion of mines. Other causes of accidents are: By or on cars (struck by cars, riding on cars), hoisting machinery and falling down slopes. Many could be avoided by few simple safety rules, main one being "Don't take chances." Keep off slope haulageways. Keep away from ropes, sheaves, drums, etc., even when they are not in motion. Don't try to jump on moving trips, don't ride on front end of trip or between cars, keep as low in car as possible, don't get off cars while in motion. Don't try to coast down slope in car which is not hitched to hoisting rope. Always keep safety-block in position to protect slope, except when cars must pass it. R. H. KUDLICH, *Coal Industry*, 4-22, 1000 w. CJW.

Uses of Concrete in Mines. Covers uses for shaft linings, shaft timbers, gallery linings, bulkheads and stoppings, shops, track ties. ANTON S. ROSING, *Canadian Mining Jour.*, 5-26-22, 3500 w. CS.

GLASS POTTERY

New Uses for Unbreakable Glass

THE development of unbreakable glass, termed "bullet proof or non-shatterable glass," is likely to prove of great value to industry. The *National Glass Budget* reports that it is now being introduced in over 100 different industries.

In automobile windshields and in the enclosing of automobiles, bullet-proof glass will be particularly useful, for not only does the breakage of windshields result in considerable loss to the owners, but statistics show that 53% of the injuries due to automobile accidents come from flying glass. Instru-

ment manufacturers are also said to have found the new glass to be satisfactory as covers of delicate instruments; and it is said to be especially adaptable to welders' goggles and for various other safety equipment.

As a protective measure for their employees and capital, many banks are having cages enclosed with bullet-proof glass, as it will resist the impact of a .45-calibre bullet fired at close range and will permit attaches to reach points of alarm in cases of attempted robbery.

Glass Making. Interesting and illustrated article on history of manufacture of glass in U. S. Reasons for adding lime, lead, etc. A. W. BITTING, *Pacific Drug Review*, 5-22, 1200 w. CJW.

Pyrex. Discussion of development of work of Corning Glass Works in producing glass of low linear expansion in such way that melting and working qualities of glass would not be affected. Not substitute for Jena and other foreign glass but better than these. Glass bakes food more rapidly and thoroughly than ordinary utensils of metal, due to greater reflectivity of metal for radiant energy. Some of its uses are: Cooking utensils, oven door panels, percolator tops, gage glasses, cylinders, tubing, laboratory apparatus, battery jars, lantern globes, chimneys, condenser lenses and headlight glasses. W. H. CURTISS, *Glass Industry*, 6-22, 1400 w. CJW.

Analysis of Optical Glasses. General details, reference being made to former articles for most of detail. J. B. KRAK, *Glass Industry*, 6-22, 500 w. CJW.

Reflecting Telescope Disks. These may be made by casting glass into suitable mold and annealing. Annealing schedules of Adams and Williamson have been found to be satisfactory. Electric or gas-fired furnaces may be used for obtaining uniform temperature necessary, but gas furnace has been found to be more reliable. Special equipment is required for obtaining accurate cooling rates and Leeds and Northrup electrical control and Robertshaw gas regulator are suitable when slightly modified. If reflector disks are made of low expansion glass change of figure in parabolic mirror due to change of temperature can be minimized. D. E. SHARP and W. H. RISING, *J. Ind. Eng. Chem.*, 6-22, 5000 w. CJW.

Stained Glass. The first of several articles on how windows of stained and painted glass are made today by craftsmen. JOSEPH G. REYNOLDS, JR., *American Architect*, 5-24-22, 3000 w. EMCC.

Stained Glass. The historical period. Second of a series of articles by a craftsman. This is a history of colored glass making from the 11th to 16th centuries, with illustrations. JOSEPH G. REYNOLDS, *Amer. Architect*, 6-7-22, 3000 w. EMCC.

Heat Balance for Glass Tank. Proper

design of glass furnace necessities calculation of amount of heat needed to melt and fine desired quantity of glass in shortest time consistent with economy and quality of finished product. Efficiency of even most modern and best built furnaces is not much over 10%. Important to know how great percentage of heat is needed for production of glass, how much to heat tank blocks or pots and how much is lost or wasted. Series of calculations given in present article to furnish such data. First installment covers efficiency of producer, line losses, composition of batch and amount of glass made in 24 hrs. F. J. DENK, *Glass Industry*, 6-22, 2000 w. CJW.

Gas Producers. In hand firing, charging should be divided through even periods and only one producer at time dumped. Air portion of producer gas (that produced by complete combustion of carbon on bottom layers of fuel bed) is most important factor in production of economical producer gas. In production of water gas portion of producer gas necessary to keep coke very hot. Done in producer by continuous combustion of lower fuel layers of producer by oxygen of air. Expensive and very little attention given to it. Less steam can be used, using low pressure or waste steam, by keeping soft and even ash bed. Automatic or semi-automatic machines eliminate many of disadvantages. Continuous changing of gas composition and varying rates of flow have deleterious effect upon both pot and tank furnaces. Steady fuel supply which produces combustion which fills furnace with clear bright flame is recommended. Good technical control is essential. H. W. HESS, *Glass Worker*, 5-27, 6-3-22, 2000 w. CJW.

Removal of Dust from Producer Gas. Dust varies from 2 to 18 grams per cubic meter of gas. Cleaning of gas usually accomplished by diminishing speed of gas through enlargements of gas flues into dust chambers and through changes in direction of flow of gas. Description of new system, based on Cottrell's patents in America and Moeller's patents in Germany. Efficiency is 99%. Handling of machinery very simple because parts highly charged are not accessible and also because of low amount of current. Power requirements amount to few kilowatts and might be generated by waste heat. *Glass Industry*, 6-22, 500 w. CJW.

Scope of Magnetic Separation in Glass Plants. Process has two main applications: use of magnetic pulleys as head pulley for conveyor belts, and self-contained separators. Latter can be portable outfits. Magnetic pulleys operated by 110 or 220 volts, DC current. Application of higher intensity separators for removing iron from glass sands presents a highly specialized problem. Iron leaves specks in glass or if finely divided causes the green color noticeable at edge of fractured pieces of thick glass. Method of installing pulley is described. R. A. MANEGOLD, *Glass Worker*, 4-22, AMC.

Amsler-Morton High-Duty Port. Heat transfer affected by conduction, convectional radiation. Conductivity of glass almost zero. Correction of little use. In tank furnaces heat is applied from above. In case of melting in pots correction is of assistance but not until after glass is fluid. Ebullition due to formation of gases from its chemical reactions also assists in a pot. Usual "seed trouble" due to the inclusion of these gas particles in the glass as it is drawn downward toward the throat faster than the gas will rise through comparatively viscous molten glass. On the other hand radiation accounts for the greatest amount of heat transferred to the glass from the flame in the furnace. In a tank furnace heat transferred from the flame to the bath by radiation. *Glass Worker*, 5-15-22, AMC.

Pyrometers in Glass Plants. While use of pyrometers has become almost universal in glass plants, author doubts if users get full value from readings, methods of setting up and establishing proper control. Article deals mostly with high temperature couple control. Some special precautions required to maintain absolute temperature regulation from day to day. HENRY W. HESS, *Glass Worker*, 6-10-22, 1500 w. WRB.

Advisable to Buy Copper Products Now

BECAUSE it is believed that the bottom has been reached in the prices of unwrought copper, the buying of finished copper and brass products in May was stimulated to such a degree that the consuming industry as a whole is reported to have increased its active plant capacity from 20% to 15%.

Automobile manufacturers were among the most active buyers of brass products, including feed-pipe, tubing, mountings and cylinders. Although earlier in the year most of the automotive makers had considerable supplies of brass and copper, these have now been reduced to a low point. Accord-

ing to the *Steel and Metal Digest*, a number of large orders have been placed and prompt delivery requested. In the Lake territory rolling mills and foundries are reported to have been running close to capacity, with orders on hand sufficient to keep the mills active from 60 to 90 days.

Quite a revival is being experienced in the demand for brass valves for both domestic and foreign shipment. This demand was active enough to absorb considerable stock accumulated during the dull period. April business was greatly in excess of March, and May showed improvement over April.

Monel Metal, a Natural Nonferrous Alloy. This unusual metal has many remarkable properties, and wider knowledge of these would bring about a greater use of it. It is a natural alloy, the ore as dug in Canada containing nearly 65% copper, about 30% nickel, slightly more than 1% iron and the balance other metals. As a foundry proposition it is difficult to handle, because it will not flow readily, and this difficulty cannot be overcome by extra heating, because it is hot-short. It chills quickly, and has other drawbacks. The metal produced, however, is a clean whitish gray, not unlike aluminum. It takes a high polish and holds it almost indefinitely, as it will not tarnish. It is very hard and can be finished as finely as desired. It will not rust and is not effected by water or moisture. It is practically acid and alkali proof, and since it is very dense, can be used in situations where corrosive liquids under pressure must be resisted. This article, the conclusion of a series, describes the Monel Metal Prod. Co. own shop methods. MORRIS A. HALL, *Brass World*, 4-22, 2875 w. MAH.

Platinum Substitutes. Gives properties of platinum making it valuable in jewelry and industry. The sources of platinum and the methods of mining and concentrating. Discussion of world's reserves of platinum. Present annual consumption exceeds the supply. Fluctuations in price. Substitutes are "palau," gold and palladium alloy, which resists many chemical reagents as well as platinum does, and "rhotanium," which is a substitute for platinum in electrical heating units. White gold is an alloy of gold with metals allied to platinum. For technical purposes a nickel-chromium-tungsten alloy (relay contacts and dentistry) and a silver-palladium-cobalt alloy (electrical) have been used. *Pacific Ports*, June 1922, 1200 w. APS.

Hot-Pressed or Forged Brass. Advantages of the percussion power press using hot metal blanks to produce a homogeneous full forging. Variety of products made from brass. Nickel, copper, tin, etc. are handled cold successfully. L. S. LOVE, *Iron Age*, 6-8-22, 1800 w. APS.

Properties of Metals and Alloys at Low Temperatures. Various metals as used commercially were tested for hardness

and resilience at -20, -80 and -120 deg. Generally speaking the hardness increased as a result of cooling, but the resilience became less. The exceptions to the latter were mainly among the ferro-nickels, and the aluminum alloys. *Aviation*, 5-1-22, 500 w. MAH

Welding Duralumin. Up to now, the welding of this alloy of aluminum has been considered impracticable, but its wide use in aircraft has forced investigation leading to the welding of the material. The author, metallurgist with the Naval Aircraft Factory, tells of this experimental work, the methods employed, results obtained, conclusions to be drawn from it. As a conclusion, he says: "It seems practicable to apply welding in the fabrication of duralumin, provided (a) care is taken in design to facilitate welding, to avoid difficult and complicated joints, and to take care of expansion strains, and (b) provision is made for heat treating the entire part after welding, or for protecting it from exposure to moisture." HORACE C. KNERR, *Automotive Industries*, 5-4-22, 5400 w. MAH.

Dependability of Cast Iron Welding. Almost perfect results can be obtained if the casting properly repaired for welding by preheating and annealing. Typical examples of difficult problems in welding castings have been successfully

solved by proper heat treatment. Eight figures. G. O. CARTER, *Acetylene J.*, 5-22, 2500 w. APS.

History of the Wire Drawing Industry. Wire drawing (as distinct from wire manufacture in general) is 1000 years old. The development of the industry with copies of old prints, etc., from the earliest date to the most modern equipment. Very interesting and readable history. Twenty Figs. KENNETH B. LEWIS, *Raw Material*, 5-22, 7000 w. APS.

Metal Spraying for Rust Resistance. Schoop process coats metallic and non-metallic objects with an adhesive coherent continuous coat. Description of apparatus and its action. Coated objects can be rolled, stamped, pressed, drawn, etc., without coating separating. Any metal can be used as coating metal. *Raw Material*, 5-22, 1800 w. APS.

MACHINERY

Better Outlook for Machine Tools

ACCORDING to *Machinery*, definite improvement has taken place in the machine-tool industry. Many of the shops entirely closed during part of last year are operating and some of the larger plants that have been running on extremely conservative schedules have put on increased forces. The activities in the radio field have affected the sale of small automatic screw machines to a considerable degree; and while most of the work in the tool shops comes from the automobile plants, some die work has also been placed by the radio instrument shops.

A growing appreciation of the work of the shops specializing in tool design and construction is indicated by the increased

buying of tool equipment from such shops by manufacturers who used to do their own tool work.

An encouraging feature of the increased demand is that although much of the buying is done on a price basis, there are buyers who continue to insist on quality in workmanship and materials. It is believed that as soon as business in general becomes more active higher prices will be paid. In this respect it is probable that the machine-tool business will follow the procedure in the iron and steel business where prices came down to a low level some months ago, but have since stiffened and have stabilized at a higher level than that to which they first receded.

Planning in Large Contract Plants. This is another instalment in this series. Article discusses installation of planning department, proper personnel, functionalizing, planning and dispatching, concentrating and centralizing the planning, decentralization and the extent of this, transportation within plant, storage of equipment and large numbers of parts, and similar topics. GEORGE H. SHEPARD, *Machinery*, 5-22, 4400 w. MAH.

Standardization of Jig and Fixture Design. Many of the parts entering into the construction of jigs and fixtures are so very similar from one job to another that they can readily be standardized, with a subsequent large saving of time and money. Special reference is had to shoulder screws, fixtures, keys, knobs, shoulder drill bushings, binder handles, eccentric type clamping handles, cranks, bases, and other parts. Drawings and dimensions. *Machinery*, 4-22, 1700 w. MAH.

Keeping Lathe in Serviceable Condition. Lathe is still the premier machine tool, especially for small shops, but to be usable it must be kept in good condition.

Accurate alignment is necessary, absence of vibration, rigidity of parts, equalized tool pressures, elimination of wind from the bed, accurate center bearing or the spindle, accurate alignment of the spindle, and other small points. All of these must be watched, the author points out, to produce satisfactory, accurate work. H. ALTON, *Can. Machinery*, 4-6-22, 3900 w. MAH.

Sine-bar Fixture for Accurately Checking Thread Angles. The sine bar is widely used in machine shops, now-a-days, especially for testing screw threads and other work not parallel with or at right angles to the axis of the machine tool. This article describes a fixture with which it may be used, and when so used it is very accurate as a means of checking angles, and as such is especially desirable in making screw-thread plug gages, hobs, taps, and similar parts. The article describes the fixture thoroughly, as well as its use, the whole being well illustrated. *Machinery*, 5-22, 800w. MAH.

New System of Bevel Gearing Developed by Research. An investigation

was conducted by the Gleason Works to determine the most quiet form of bevel gear tooth consistent with strength and durability. As a result of this thorough research, a new system has been developed, in which the addendum and dedendum for a pitch vary with the ratio, and are usually different for pinion and the gear. Similarly, the pressure angle depends on the number of teeth and the ratio. Details are given of the research work, the data obtained are presented in part. The new gear shape is shown and described, and much other interesting material. F. E. McMULLEN and T. M. DURKAN, *Automotive Industries*, 5-18-22, 5100 w. MAH.

Double-End Center-Drive Lathe for Production Work. A detailed description of the new Greenlee lathes, which are built in 36 and 60-inch sizes. On fairly long work, such as rear axle shafts, it is possible to work on both ends simultaneously with this machine, so that the production time per piece is practically cut in half. P. M. HELDT, *Automotive Industries*, 5-18-22, 2000 w. MAH.

Tooling Equipment for Pistons. Description of the use of automatic machines and special equipment for machining lynite pistons at a high rate of production. The article describes the machines, the pistons, the tools and their method of use, also the fixtures needed. The illustrations are equally complete. EDWARD K. HAMMOND, *Machinery*, 5-22, 3100 w. MAH.

Portable Saw Bench for Pattern Shop Use. Description of machine used for this purpose. Dimensions are given. *Iron Age*, 4-6-22, 400 w. IG.

An aerial view of the famous Krupp Works at Essen, Germany, showing the great plant going full blast. Krupp is now manufacturing an almost endless line of metal products.—(Union Trust Co., Cleveland.)

How Washable Maps Can Help You Sell

**4-Wing Multi-Unit
Fixture**

Displays eight of our large washable maps, all of which may be turned in either direction or spread apart as shown.

**22-Wing Multi-Unit
Fixture**

Displays 44 of our large washable maps. Will accommodate the complete series of State maps. All wings may be swung in either direction.

On "Namapco" washable maps you can outline or shade different territories—indicate the location of distributors, branches, dealers, agents, etc.—show the towns where you have dealer representation and where you do not—mark down sales quotas, daily, weekly or monthly sales totals, and various other sales and distribution facts.

When changes in the marking are necessary—as they will be from day to day—simply wash the map as shown above, using either a sponge or damp cloth. Crayon markings may also be removed with art gum. The surface of the map is left smooth and clean, and is then ready for new marking. Map tacks may also be used to show additional information. In this way you can keep the daily changes and developments in your sales campaign before you, and know at a glance just where you stand.

We shall be glad to send you literature telling how many of the largest business concerns in the country use washable maps in their sales departments. It will help us to make definite recommendations if you will tell us what territory you cover.

Address Dept. 1D-6, Murphy Bldg., Indianapolis, Ind.

This graphic picture of your territory will often reveal many fertile sales fields that have not been thoroughly cultivated, and suggest changes in territorial divisions, salesmen's routings, distributors' locations, etc., that will mean decreased expenses and increased business. It will also enable you to keep in close and constant touch with all your sales representatives, to know where your salesmen are, and to coordinate all of your selling efforts.

These washable business maps may be had in either the large size for display on our large Multi-Unit System (size of wings 50 x 48 inches) as illustrated at the left, or in a smaller size (21 x 28 inches) for display either on our small-size Multi-Unit System or in map tack cabinets. Both the large and the small maps have a complete index on the front surface.

OILS • PETROLEUM

Crude Oil Stock Accumulating

IN the opinion of the *Oil Weekly*, the crude oil market is no nearer stabilization today than it was several months ago. Since the first of the year 40,000 barrels of crude oil have been going into storage every day. It is estimated that this country now has about 150 days' supply of crude oil above ground. And although Mexican operators say that they have held down production because of falling off in demand for their crude, yet Mexico is still producing 450,000 barrels a day, and it is generally thought will probably con-

tinue to produce at that rate for several months to come.

While a large amount of oil in storage may tend to steady the market and prevent up and down flurries, the producer faces the danger of the purchasing companies arriving at the point which they have figured as the "stabilizing point" with production still far in excess of demand. It is pointed out that if the present rate of production in the United States is maintained, the producers may be forced to go into the winter with a continued oversupply of crude oil.

Future Demands on Oil Industry of U. S. A careful analysis of the situation with graphical charts to show the relation between consumption and production of crude petroleum, gasoline, kerosene, lubricating oil. Empiric methods of forecasting demand are indicated. Demands for crude petroleum for the next ten years will be determined by the growth of the automotive transportation and motor fuel requirements resulting therefrom. Future demands of crude petroleum and its products may be estimated by methods of empiric projection, but such methods are found to be unsatisfactory. Two rational methods of forecasting the demand for gasoline are described and applied and a method involving the principle of diminishing returns is advanced as the most satisfactory approach to the problem. By means of the method involving the principle of diminishing returns domestic demand for gasoline is estimated to be 6800 million gallons in 1925 and 8300 million gallons in 1930. Concluded that 585 million barrels of crude petroleum will be sufficient to support automotive transportation in 1925 and 580 million barrels in 1930 on the basis of a continuation of recent progress in technology. J. E. POGUE, *Oildom*, 5-22, 8000 w. IG.

Ramage Process a Success. New method of cracking oil which consists in passing oil vapors over iron ore in closed tube. The oil vapors are mixed with steam. Process is claimed to be much easier and cheaper to operate, is easily installed and yield of gasoline is increased. Yield of motor spirit, with the use of gas oil, has developed from 73% to 85% gasoline. Gas taken off the apparatus is used to heat the same. Iron ore is of nominal cost and does not deteriorate on usage. Product is free from carbon-forming compounds. By its use the "knock" in the motor is almost entirely eliminated and a 25% increase in power is obtained. Product is called "super-gas." J. B. WALDO, *Oil News*, 5-5-22, 1200 w. IG.

China Wood Oil. Gathering of nuts in China and method of manufacturing the oil are discussed. G. H. PICKARD, *American Paint Jour.*, 3-27-22. IG.

Recovery of Gasoline from Uncondensed Still Vapors. By more complete condensation of still vapors at petroleum refineries, 120,000,000 gallons of gasoline may be added yearly to national output. It is estimated that 50,000,000

gallons were recovered in this way in 1921. Condensation of vapors formed by heating crude oil is effected in refinery by leading vapors through coils of pipes submerged in water. On cooling, most of vapor becomes liquefied, but certain amount of vapor, due to insufficient time for proper cooling or to fact that its condensing point is lower than temperature of water, will remain uncondensed. Methods are shown for collecting vapors. Small vacuum is held on run-down lines where vapors are trapped off by means of goose-necks. This gas passes through traps which remove any condensate carried in the lines. Vacuum is held by either intake of compressor or in larger installations by means of exhauster. When gas of high sulfur content is encountered, unit for removal of sulfur must be installed. This is accomplished by scrubbing gas with solution of caustic soda or suspended solutions of oxides of iron or lime. In recovery systems, compression process is more common and consists of compressing gas to high pressure and cooling. Absorption process consists of absorbing gasoline from gas by passing through lower gravity distillate. When naphtha is used as absorbent, it is raised to gravity where it may be marketed as gasoline. When heavy oil distillate is used, gasoline is separated by distillation. Combination of two methods is made use of when gas after compression is passed through absorption towers. General figures are given of cost of construction of recovery plants based on capacity of refinery. D. B. DOW, *Reports of Investigations, Bureau of Mines*, No. 2344 (1922), 25 pp. CJW.

Brown Fractionating Shale Oil Retort. Consists of horizontal rotating cylinder about 30 ins. in diameter, constructed in three sections of 24 ft. each, to make a total length of 72 ft. for the retort. Helical lining of the retort transports the shale from the feed end to the discharge end. Fire brick lined furnace surrounds each horizontal cylindrical section, so that each section may be heated to a different temperature. System very flexible, wide range of temperatures and speeds of travel of shale being possible. Outlet pipe for each section leads to separate condensers so as to produce various fractions of oil. Relatively large pieces of shale rock can be handled by this apparatus. F. E. SHEPARD, *Engineering World*, 5-22, 2400 w. IG.

Crankcase Dilution. Dilution is caused through the mixing together of the heavy hydrocarbons of the lubricant with the higher boiling point hydrocarbons from the fuel. Crankcase oil regeneration consists of process in which fuel and water dilution are automatically removed and the sediment, composed of carbon particles, sand and minute pieces of metal, is filtered out. W. H. PARISH, *Oil News*, 5-5-22, 4500 w. IG.

Location, Design, Construction and Operation of Distributing Warehouses. A continued article describing various details regarding distributing warehouses used in the oil business. It is indicated that there is less standardization along this important line than in any other connected with the oil industry. Location must be determined from standpoints of availability to trade and source of supply. Character of the soil on which the warehouse is built plays an important part in determining the efficiency of the warehouse. Size and shape of tanks should be selected with the utmost care. Adequate storage facilities are important. Storage tanks should be made very carefully and should be absolutely tight. Not necessary to bury tanks in the ground. This is very expensive procedure. W. B. GOOLSBY, *Oildom*, 5-22 IG.

Welding in the Oil Fields. Welded joints are standard for new pipe line construction. Prairie Pipe Line Co. of Independence, Kans., has completed 140 miles of 8-in. pipe. Gives details of methods, etc. *Welding Eng.*, 4-22, 1200 w. APS.

At the Pittsburgh, Pa., experiment station of the Bureau of Mines, tests have been made in a small gallery to obtain comparative data as to the sensitivity of methane and gasoline for the contemplated research as to the safety of motors in gasoline vapors. Permissible equipment, which has been tested by the Bureau of Mines and more carefully inspected by the manufacturer, rather than "flame-proof" equipment, should be required in all gaseous mines or gaseous sections of mines and the use of any other should be discouraged.—*Bureau of Mines Bull.*

BIGGEST PROFITS IN HISTORY

Due to Industrial Engineers

Mr. William M. Regan, President of

REGAN BROTHERS, MINNEAPOLIS, says:

SKEPTICAL—
*Thought their
Business was
"Different"*

"When L. V. Estes Incorporated, told us about ten years ago that they could come into our wholesale bakery and cut down our costs by industrial engineering ideas that had proved successful in a piano factory, for instance, we were like many other business men, skeptical—'our business is different.'

"To our surprise and delight, though, the first visit proved Estes' genius for making practical improvements in a totally new situation. The changes they recommended have never been revolutionary, but when one multiplies a very small unit saving by 20 million loaves per year, he finds a total cost reduction that is tremendous.

"Our first year's savings in the delivery department alone more than paid for the whole service, and these savings have gone on ever since.

"We are glad that our recommendation induced a shovel concern in another state, a manufacturer in Indiana, and a large concern in our own city, as well as several other members of the Bakers National Association to follow our example and profit by Estes Service in the same way.

"Estes men have returned several times in the past 10 years as our plant grew, and have always been popular with foremen and executives alike. It requires tact to show a technical expert where some other method is better and easier than his own, in his own specialty—but Estes not only does it, but has our experts enjoying and taking pride in this saving of waste.

"After Estes started us along new lines of economy our gross profit and percentage of profit were higher than they had ever been in our 30 years in business."

Insurance Policies with Your Paper

IN an effort to increase their circulation many newspapers in England are offering accident insurance at greatly reduced rates to subscribers. It is reported that the competition among various newspapers that have adopted this policy is resulting in almost incalculable liabilities. The insurance companies are declining to underwrite anything but legitimate transport risks and are said to be strongly opposed to the piling up of claims so that they may be employed by the newspapers as daily "advertising points." It is now reckoned

that two or three of the London papers are offering indemnities against the accident risks of man and wife which will cost from half to two-thirds of their total revenue from sales. While the offering of insurance policies by newspapers is not illegal in England, it is believed that their cost will soon become prohibitive. Twelve months of the present accident and disease benefits will cost one of the London journals at least a half million sterling. Other newspapers are accumulating burdens almost as heavy.

Evolution of Bookmaking. Earliest records of books are sheets of stone, brass and lead or tablets covered with wax on which writing was engraved. Egyptians discovered writing on papyrus. Introduced use in Greece and Italy, but, due to scarcity of papyrus, vellum and parchment were used. These, like papyrus, were rolled up on roller of wood or metal. For convenience someone thought of cutting two sheets of vellum same size and sewing them together; so book evolved. Scribe wrote entire book, made own ink. Book sent later to rubricator, who added capital letters, the colophon and liturgical directions. Demand for these books so great that block books were introduced to multiply more rapidly manuscript volumes. (Continued.) JAMES MACLEHOSE, *Ben Franklin Monthly*, 5-22, 1000 w. MBB.

Future of Color Work. Improvement made in color work in future must depend on non-filter plates for color photography. Present orthochromatic photography not useful for three-color work. They show possibilities exist of making plates which require no filter. Should be possible to make improvement in illumination of original. Arc light too violet; daylight best illuminant for color work. Three-color inks generally used to produce black by superimposing them. But it was only rough application. Necessary to establish four-color process now that error of supposing red and green made yellow, has been proved. Natl. Lithographer, 522, 600 w. MBB.

Hints About Embossing. Printing and embossing done at one operation in using alabastine, as it is considered that counter made from this powder will last longer than anything else tried. Alabastine brings out all letters and details, and after mixing composition for some time is possible to spread it without cutting away, which is saving on all jobs. Extra impression will not make embossing deeper if it is not in die. JAMES J. MCGILL, *Amer. Pressman*, 5-22, 500 w. MBB.

Care of Flatbed Presses. Life of machine dependent upon care received. Important that operator should study ma-

chine and instruction book carefully. First fundamental principle in care of printing press is leveling. Press stand-

READERS WHO GOSKIMMING THROUGH BOOKS NOWADAYS HELPED TO AN EASY UNDERSTANDING OF THEIR CONTENTS BY THE USE OF CAPITALS AND SMALL LETTERS SPACES BETWEEN WORDS AND PUNCTUATION MARKS PARAGRAPHS AND ITALIC SHAD-
LY EVER GIVE A THOUGHT TO THE TROUBLE PEOPLE LONG AGO HAD IN OBTAINING INFORMATION AND INSTRUCTING FROM THE PRINTED MANUSCRIPTS AND BOOKS OF THAT DAY FORMANCENTURIES EVERYTHING WAS PRINTED LIKE THIS IN CAPITALS ONLY WITH NO SPACES BETWEEN WORDS NO PUNCTUATION MARKS AND NO REGARD AS TO HOW WORDS WERE DIVIDED AT THE END OF THE LINES

Small letters were unknown until about the seventh century, and even after their introduction the capitals continued to be used much more than they are now, while the few punctuation marks first employed by the grammarian Aristophanes of Alexandria, about the middle of the third century before the Christian era, did not come into use until the Venetian printer Aldus Manutius used them with striking effect about 1500. In short, the printed page as it is known to us is a very modern product. Perhaps the contrast between the ease with which you have read this paragraph and the difficulty you had in reading the preceding one will help you to appreciate more fully your present-day advantages.

Unfair Use of Capitals

Because capital letters in typography are being used less and less as we study legibility, and are becoming unpopular, is no reason why they should be treated unfairly. The accompanying clipping is from our well-known *Ladies' Home Journal*, which is demonstrating to its readers how difficult it is to read capital letters in a mass and how easy it is to read lower case. Why were the spaces left out between words in the capital group? No wonder the group is hard to read. Leave out the space between words in the lower case and do not divide the words properly and the lower case too will be difficult to read.—("Fair Play," in letter to the *American Printer*.)

ing on anything but solid foundation is likely to "go out of level" during first months; should be leveled occasionally during first year and possibly afterward. Always look machine over carefully before throwing switch, even then turn over for complete cycles before throwing into high. Oil everything that moves at least once a day, harder worked parts twice. Adjust to prevent wear and to secure perfect work. In case of chronic misregister, begin at bottom and work up. Give careful attention to each unit. Keep press clean. FRED S. ENGLISH, *Amer. Pressman*, 5-22, 1000 w. MBB.

Why U. S. Newspaper Law Should Be Codified. National commission to draft and perfect code covering all branches of law. Action by legislatures of States suggested. JOHN H. PERRY, *Fourth Estate*, 5-20-22, 500 w. MBB.

House Organs, Wheezy and Otherwise. Hardly business today that would not be better off if issued proper house organ. Beware professional house organists. Editor and chief contributor should be head of concern or near enough to it to exercise right of saying what is most advantageous for customers. These often have little idea of what firm is ready and willing to do for them. Such data should be right and proper province of house organ. H. L. CLEVELAND, *Office Appliances*, 5-22, 2000 w. MBB.

Selling Printing with Help of Dummies. Use of dummies nearly always essential to securing of important orders and contracts. But waste in their use is tremendous, due to lack of care in planning. Most feasible to visualize printing job complete before setting type or making engraving. Have sketch dummy complete, lettering all indicated, pictures sketched in, photostats and silverprints in exact position; complete proposal for printing, including blank dummies showing exact kind and weight of paper stock to be used. Such dummies please prospects and gets them to rely on firm for service. Another effective dummy service is complete direct-advertising plan to cover number of mailing pieces to be distributed over certain period of time. WILLIAM A. KITTREDGE, *Amer. Printer*, 5-20-22, 1500 w. MBB.

Discounting the Count

A COUNT used to be a man in charge of a count of 500 persons to whom he was a sort of overlord. This is not true today because of altered political conditions. We still have Counts, but the Count business has changed somewhat.

Business, of all kinds, has undergone something of a revolution. It was not so many years ago that pack peddlers were the sole distributors and transporters of many of the household articles of the day. Their legs set the limits for most distribution problems in those days.

Modern transportation, progressive sales methods—and *advertising*—have broken the shackles of time. They make a speedy job of what used to take years. Through advertising many an article has been introduced simultaneously in stores all over the country.

Advertising today is the method used by business to tell you why you should have certain goods and how to identify those goods. The advertisements you find here are a truthful *catalog* of needed merchandise.

Articles of all kinds and for all purposes are presented in a pleasant way through the medium of type and picture. The outstanding requirements of every member of the family are met by offers of good merchandise of proved value.

*Use the advertisements for guidance
and you will be a constant gainer*

PAPER

Higher Prices for Newsprint Probable

THE fact that consumption of newsprint paper during March was greater than during the same three months in the "banner" year of 1920 is believed to indicate that a rise in prices may be expected in the near future. At the end of March the number of days' supply in the hands of the American publishers was lower than it had been since May 31, 1920. At the same time the number of pages being printed by the larger newspapers of the United States was greater than it was in either 1920 or 1921. And it is pointed out that this combination existed in the newsprint market before the last increase in prices. The accompanying tabulation of percentages of increase shows in concise form the recent improvement which has taken place in the consumption of newsprint.

NEWSPRINT PAPER CONSUMPTION IN U. S., 1922 AND 1921

	% Increase Over 1920	Corresponding Period of 1921
1922		
January	6.5	10.4
February	6.8	10.7
March	9.7	9.9
Percent of increase during first two months of 1922 over that during		
First two months of 1920.....	6.9%	
First two months of 1921.....	10.6%	
Percent of increase during first three months of 1922 over that during		
First three months of 1920.....	7.7%	
First three months of 1921.....	10.3%	

Oat Hulls for Strawboard and Paper Pulp. Results of semi-commercial and mill runs on oat hulls indicate they are capable of utilization in manufacture of board using digestion with lime in same manner that straw is treated. Yield obtained and character of stock indicate cost of converting oat hulls to board would not exceed cost of converting straw, and in yard and rotary room labor savings of approximately 50 cents per ton of product are possible. Also saving in steam required for drying. Bursting strength of sheets made from oat hulls not as high as from straw board, but satisfactory results obtained by mixing oat hulls with equal portion of straw. Tougher sheets obtained by cooking small amount cotton linters with hulls together in rotaries. S. D. WELLS, *Paper Mill*, 5-20-22, 4000 w. MBB.

Molding of Chemical Pulp. All kinds of pulp may be attacked. Description of spores, which are always present in air. All pulp as manufactured well infected unless run directly to paper machine. Requirements for development are food, air, suitable degree of warmth and moisture. Protection may be obtained by poisoning with antiseptic material,

such as sodium fluoride, storage at low temperature, or drying pulp before storage. R. J. BLAIR, *Pulp Paper Mag.*, 5-25-22, 800 w. CJW.

Freeness Testing of Pulp. Advantages of maintaining stock at desired degree of freeness are: In grinder room, increased production at decreased hp. per ton, by knowing immediately when stone needs dressing or burring, and not allowing power to be consumed indefinitely and unproductively by dull or glazed stones. In beater room to determine degree of beating and thus avoid losses in machine room because of variation in stock. Complete outfit described for testing freeness, arranged on and in cabinet described and illustrated. F. M. WILLIAMS, *Paper Mill*, 6-3-22, 1000 w. CJW.

Methods of Furnishing Stock. These are: Rolls or baled sheets, hydraulic pressed sheets, moist laps or sheets, drainer stock, needles, and slush. Three general systems for preparation of stock, beaters, mixing tanks and continuous mixing systems. Methods of measurement complicated by variation of moisture content. *Paper Trade J.*, 6-1-22, 500 w. CJW.

Half-Stuff from Waste Papers. Four operations involved, sorting, dusting, cooking and washing, of which last two are in state of rapid development. Carrier system and screen system compared: cost favors the former, quality the latter. In case of rotary and vat cooking processes only slight shredding and light dusting are necessary. Vomiting tub, rotary and vat processes of cooking compared. Rotary can cook paper stock just as economically and well as any other process in use at present time. Beater type of washing both wasteful and inefficient. May be replaced some day by intermittent washer. Continuous washer is ideal theoretically, but has several practical disadvantages which will greatly hinder its general adoption by paper mills. E. G. MILHAM, *Paper Mill*, 6-3-22, 2500 w. CJW.

Manufacturing Wood-Pulp in Maine

The material in the foreground that looks like blankets is pulp in "laps." This pulp is shredded in "binders" into fibres, and it is from these fibres that paper is manufactured.—(© International.)

Where Are Your Customers?

The continued revival of purchasing activity is assured.
Some business men are *waiting* for the flood tide;
others are going to *meet* it.

It is advantageous to know not only *when* to expect business but also *where* to expect it. The current Forecaster tells specifically why purchasing activity will come earlier in the cotton growing than in the grain producing sections. It is well worth reading, and should enable you to make a fair estimation of the value of the Brookmire Service, which answers innumerable other perplexing questions.

Send for a free copy of Forecaster DD today.

Manufacturing Tires for Orders—Not Stock

OWING to the frequent spurts and slumps in tire building, involving the laying off and returning of men, tire manufacturers have stopped expanding finished goods inventories and are applying production direct to sales. According to *Motor Record* they are determined never to be caught, as they were in 1920, with a huge supply of tires on hand. Scarcely a company has an inventory exceeding a 60-day tire supply based on normal sales. The extent to which this policy is carried is evidenced by the fact that in many cases

tires are wrapped and loaded in freight cars while still warm.

There is, however, a steady increase in the output of practically all plants. As compared with January of the current year, this increase ranges from 30% to 50%, while the increase over May, 1921, ranges from 25% to 100%. Although mechanical goods lines have been slower to recover, recent months have brought a very satisfactory increase in orders. Rubber sundries, novelties and footwear reflect an encouraging outlook.

Tapping Experiments. This article is concerned with a series of experiments that were performed on rubber trees to ascertain the effect of different methods of tapping the tree on the yield and quality of the rubber obtained. The experiments were carried out on trees of various ages. *Rubber Age*, 4-10-22, 1700 w. IG.

Use of Magnesia in Rubber Industry. History of application of magnesia in rubber field. Several types of magnesium carbonates employed. Properties of various carbonates described. Carbonate of magnesia can be used to considerable proportion in admixture with rubber. Since slightly basic it accelerates cure in small degree. In conjunction with zinc oxide it produces tough, stiff compound suitable for use on tire tread or for truck tires. Said to increase abrasive resistance of rubber stock containing it, but for this purpose not over 10% should be used, and compound should also have considerable quantities of zinc oxide and gas black. Primary use of calcined magnesia in rubber is to increase rate of cure. Second purpose is to dry up and

stiffen compounds containing considerable resinous or bituminous material. Use of magnesia somewhat precarious, either too much magnesia, or too much sulphur will give stock which will over-cure and harden up on standing. In this respect litharge is handled more easily, and is preferred in all goods excepting those in which black color produced by litharge is objectionable. Because of this drying up on age, magnesia can be used in ordinary soft rubber compound only to extent of 1.5% to 2% of weight of rubber. If sulphur content is very low, this may be increased to 3%. Effect of magnesia on acceleration of vulcanization of rubber is discussed as well. A. H. SMITH, *Asbestos*, 4-22, 400 w. IG.

Composition and Use of Golden Sulfide of Antimony. In the investigation made by the authors into various samples of commercial golden sulfide it was found that the assumption that the material contained the penta-sulfide was incorrect. The conclusion is drawn that commercial golden sulfide of antimony contained no higher sulfide than the tetra-sulfide. It was also indicated that

the sulfur extractable by carbon disulfide was available for vulcanization of the rubber. F. H. SHARPE, *Rubber Age*, 4-25-22, 2800 w. IG.

Methods of Analysis. Report of the committee on methods of analysis of rubber division of American Chemical Society. Discusses reasons for analysis, preparation of sample, reagents and gives methods for specific gravity, chloroform and alcoholic-alkali extract, free and total sulfur, ash, barium sulfate, antimony, free carbon, nitrogen, unsaponifiable matter and waxy hydrocarbons. *J. Ind. Eng. Chem.*, 6-22, 5000 w. CJW.

Vacuum Process of Hollow Ball Making. Description of the vacuum process of making hollow balls, a process which is revolutionizing the production of hollow rubber goods of all sorts. Calendered sheet rubber is used for this purpose. *India Rubber World*, 5-1-22, 1500 w. IG.

Importance of Teamwork in the Factory. How one can help the other in operation of a rubber mill. Checking up errors and bringing them to the attention of the proper persons or department instead of blaming a common "goat." Several interesting examples, indicating how teamwork helps to secure efficiency in running the plant, are described. A. E. FRISWELL, *Rubber Age*, 4-25-22, 3000 w. IG.

Rubber Business Thirty Years Hence. An imaginative account of how the rubber business will have progressed by 1951. Such improvements as removal of the rubber odor, self-repairing rubber, crude rubber tanning, superresilient rubber, synthetic cotton, etc., are forecast. *India Rubber World*, 4-22, 3000 w. IG.

Plastic Raw Materials and Products. Progress in development of use of papier-mâché and plastic wood as a base for decorative appliances and ornaments. Use of compressed wood fibers for this purpose has been perfected. The lightness of the product is of particular importance. *Raw Material*, 4-22, 1500 w. IG.

Temperatures of various parts of a 40 x 8 tire as obtained by several methods. The room temperature during this test was 90° F.—(*Automotive Industries*.)

House Organ Headquarters

**WILL HELP YOU ESTABLISH THAT EMPLOYEE PUBLICATION
OR SALES ORGAN YOU ARE THINKING ABOUT**

Ours is a Planning, Writing, Editing, Printing and Art Service Distinctively Qualified for House Organ Work.

Tell us how much you want to spend and we'll give you a definite idea of the publication that amount will buy. And we will furnish a Magazine or Paper that will fit into your needs.

We Specialize in Industrial and Institutional Publicity Designed to Reach the Employee

Our Service Eliminates Costly Experimentation

Have You Seen the Blue Pencil?

Send 30 cents in postage for a sample copy

The only Trade Paper devoted exclusively to the subject of Employee Publications, House Organs, etc. It deals in a Practical way with every phase of publication work.

Planning, editing, gathering news, articles and information, how to buy and use art and engravings, etc. It contains 80 and sometimes 96 pages of information.

HOUSE ORGAN HEADQUARTERS, 187 Montague Street, Brooklyn, N. Y.

The Saving Grace

as applied to magazines, means the retention of all issues which may be worth something later on. We submit that *each* copy of the *Industrial Digest* is worth saving because of the more than five hundred digests of important articles which it contains. The Annual Cumulative Index which will be sent without charge to all subscribers will make this valuable data instantly available, *provided* the copies are filed for reference.

And for this purpose we are prepared to furnish neat, strong, handsome binders, done in black cloth with gold lettering, and capable of holding a year's copies, at the moderate rate of two dollars each.

Order now and keep your copies in good condition.

SUGAR·CONFECTIONERY

Joint Advertising Campaign for Candy Makers

ACCORDING to a writer in *The Western Confectioner*, cooperative advertising by the candy industry will prove beneficial only if its purpose is to increase the sale of candy generally, not to increase the sale of some particular kinds of candy to the detriment of others. The first step should be the adoption of a slogan and, supporting the idea, the writer cites the success achieved by the florists and jewelers who built

their campaigns around slogans directly suggestive of gifts.

It is believed that the vital thing in the plan is to help the retailer sell more candy to the consumer, since it is upon the retailer that the manufacturer depends for distribution, and that the concentration of purchases on special days or occasions will secure the desired result more effectively than lower prices, appeals of food value, cleanliness or purity.

Paper Mulching for Sugar. Paper mulching of sugar cane and pineapple plants first used in Hawaii likely to come into general use in countries where intensive cultivation is required. Paper serves both to shed water that comes from excessive precipitation and to hold moisture in ground. Labor saving obtained by use of paper also important; under old system of cultivation keeping crop free of weeds cost \$30 to \$40 an acre. Use of paper eliminates this cost. Another important factor is that by use of paper mulching leaching of soluble nitrates which are used for fertilizing is prevented. Experiments in manufacture of mulching paper indicate abundance of raw materials in United States well suited for this purpose. W. D. HORNADAY, *Paper Mill*, 4-29-22. HHH.

Mechanical Harvesting of Sugar Cane. A description of the Luce machine and its work. This machine cuts off the growing cane just below the ground, strips it of leaves and surplus sprouts or other material, and cuts off the tip just above the last ripe joint. This

leaves the cane then in just the form it is needed for the grinder. Consequently the machine eliminates all hand or manual labor, and since it is self-propelled, all animal labor as well. It is said that a complete machine in full operation is equal in results produced to 45 men. The article describes the machine in detail, following the inventor all through his early struggles, and describing all of the early machines as well. *Exporters & Importers*, 4-22, 2900 w. MAH.

Sugar. Points out need for confectioners to know what they want and urges co-operation of manufacturer in furnishing particular sugars for these purposes. First must know strength of sugar and corn sirups. White running creams should be made from first run liquors and not from granulated. Refiner's syrup may be used but its eccentricities must be learned. Many problems awaiting solution and need for research laboratories is very great. F. W. MURPHY, *Candy Mfr.*, 5-22, 1200 w. CJW.

Candy Making. Changes that take place in candy kettle are loss of water, amount depending upon temperature used until at 320° F. only about 2% remains. Other changes above 240° F. are inversion of sucrose to glucose and levulose, a reaction in which time plays part. Acids and certain salts accelerate reaction. Sterilization also results. Water may have two effects: Effect upon sugar as regards inversion and its freedom from or contamination by micro-organisms. Comparatively seldom that water does not contain enough lime to render it fairly satisfactory. Candy is exceedingly free from organisms and is undoubtedly one of purest forms of food. A. P. BRYANT, *Candy Mfr.*, 5-22, 1200 w. CJW.

Gelatin. Edible gelatin made from calfskin cuttings, bones and pigs' feet. Ossein, from bones, of greatest importance. Manufacture consists in washing, soaking in milk of lime several weeks with changes of liquor, washing free of lime, adding sulfurous acid to bleach product and then boiling, heat being furnished by superheated steam. Temperature of 80-85° being rather carefully maintained. After 6-8 hrs., solution is drained off and operation repeated three to five times. Upon standing, brilliant supernatant gelatin solution is obtained, which is concentrated to consistency that will easily jelly. Then dried. Other articles to follow. R. H. BOGUE, *Candy Mfr.*, 5-22, 1800 w. CJW.

Carbonated Ice Cream. Carbonation of milk and ice cream does not guarantee the product to be a safe product. While the process may have many commercial advantages and may be of decided benefit to dairy industry, the experiments reported indicate that the process cannot be relied upon as a means of insuring sanitary quality of dairy products. M. J. PRUCHA, *Ice Cream Trade J.*, 5-22, 1500 w. CJW.

Ice Cream in Its Native Land. Formulas used by Italians for ice creams: crema gelata; sorbetto; granita; poncio; spumose; zabaglione; spumone; bombe; charlotta; marenga; bavarese. *Soda Dispenser*, 3-22, 700 w. WRR.

Candy Flowers Nowadays Are Tastefully Packed

Here is shown a girl preparing candied bouquets ready for the exclusive trade of a New York confectioner. Small "band" boxes are used for the purpose—oval, round and oblong. The boxes usually have flowered designs.—(*Candy and Ice Cream*.)

Revolutionizing Cotton Picking

ACCORDING to the *Engineering World*, the development and successful use of an improved electric cotton picker promises to supersede the hand gathering of cotton in the South.

Operating data collected during thorough trials of the cotton picker indicate that it will be possible for a person to gather from 400 to 700 pounds of cotton a day as compared with 70 to 150 pounds a day by hand. By means of this new device the cotton grower will be able to harvest all the cotton he plants, and to do so before the rains and frosts damage

the bloom and lessen the value of the crop. Among other advantages is the fact that the cotton can be picked when ripe, thus improving the grade and adding to the value of the bale. Moreover, the motor apparatus picks cotton in a much cleaner condition than by hand. Under manual labor it is estimated to take 1600 lbs. to make a 500-lb. bale of cotton lint after the seeds and dirt are removed at the gin. Electrically picked cotton shows a saving of 200 lbs. in the amount of cotton which will produce an equal size bale of cotton lint.

Spinning Tests of Meade Cotton. Table showing results of tests. Can be substituted for Sea Island. Can only be distinguished by experts. *Cotton Mill News*, 4-13-22, 1500 w. WRR.

Bleaching Cotton Fabrics. Important in manufacture of cotton goods is adjusting of scouring and bleaching process, which involves construction of fabrics for best results. Condition of finished goods is result of all processes from selection of raw material to final operation of finishing. *Textiles*, 5-22, 700 w. MBB.

Tests to Determine Efficiency of Weaving and Finishing Colored Cotton Goods. Test made to ascertain absolute shrinkage of lot of goods put through weave and finishing departments. Result supplied figures upon which to base close competitive selling prices, showed seconds exceedingly low, showing what is possible if close attention always given by everybody; rags were higher than should have been; could have been trimmed down closer, also remnants and short lengths. Good plan to measure size of filling parcels, and filling itself must be right size. Test showed pays to watch weight of warps as well. H. D. MARTIN, *Textile Colorist*, 5-22, 1500 w.

New Experience in Dyeing and Printing with Indanthrene Colors. For dyeing indanthrene colors, which possess strong affinity for fibre on artificial silk, which is used to increasing extent, add to vat some dekol and glue to insure level results. Addition of dekol acts as thickening agent to bring dyestuff in fine state of divisions as possible, and keep in suspension. Important feature in manufacture of colored cloth is fastness of indanthrene colors against chlorine. In printing cotton goods with indanthrene colors, most important part of machinery is ager. Irregularities in results always caused by quantitative or qualitative changes in nature of steam, result of rust or dirt in pipes. Dull colors caused by overheating ager are rectified

by running unprinted goods through, allowing time to cool. *Textile Colorist*, 5-22, 600 w. MBB.

Wool Blending Importance. Blender should know kind of thread he wishes to make; kind of fibres he has to use; price final thread is to cost; behavior of various wools and fibres, etc. *Canadian Tex. Jour.*, 4-11-22, 700 w. WRR.

Saponification Scouring of Wool. Four methods are used in scouring wool. Saponification claimed to be efficient cleaner; method of using this process. "Low goods" scour, use of solvents. J. SCHOFIELD, *Textile World*, 4-8-22, 2000 w.

West Australian Wools. Description of method of breeding, troubles of climate, etc. *Canadian Tex. World*, 4-11-22, 2000 w. WRR.

Dyeing Wool and Worsted Pieces. Important that dyer be kept informed of any change in mixture of wools. Fulling may be responsible for clouded pieces. Mineral soaps, from hard waters, may cause light spots in piece, due to water-proofing action. Palm soaps used in fulling with great success. Discussion of chrome mordants and assistants, the single bath chrome methods and after-chrome methods. Sulfon cyanides work much better when half their weight of bichromate is put into dye bath. All dyes should be in full solution before being added. J. A. KNOX, *Am. Dyestuff Reporter*, 5-22-22, 2800 w. CJW.

Purifying Thrown Silk. Reports of results of extracting various unsoaked raw silks with a variety of solvents; 80% to 90% of an ordinary fatty oil present in soaking bath is removed by silk; 10% of soap remains on silk, by far larger portion remaining in bath; 80% of sulfur-bearing fat of sulfonated oils remains in bath, as well as any soluble salts present from any source. Practically all oil is removed by extraction, together with silk wax and greater part of sulfonated oil, but mineral salts, oxidized and dry, saturated soda soap, will be partially left behind. Acetone or petroleum ether, containing one-fourth its volume of methyl alcohol, is good extraction agent. Time factor important, as prolonged extraction slightly affects silk substance. H. S. MUDGE, *Am. Dyestuff Reporter*, 5-22-22, 2000 w. CJW.

Dyeing Acetyl Silk. Cellulose acetate silk can be dyed directly without use of swelling agents and other costly and difficult pre-treatments. With Dreyfus process, no selling agent required. In method of dyeing untreated silk by selected dyestuffs having a sympathetic affinity for cellulose ester, basis of selection is by chemical constituent groups favorable to absorption and fixation of dyestuffs such as amino and alkyl-amino groups, hydroxyl, nitro and ketone groups. Important to wet silk in special bath to remove dirt. All basic dyestuffs can be dyed readily on acetyl silk without previous treatment. Tannin mordants are unnecessary. Temperature of dye bath should be carried up to 65° C. in two stages. Dyeing of gallocyanin dyes is closely similar to basic dyes; alizarine dyes are generally dyed from plain bath in soft water. Certain of the sulfonated azo dyestuffs can be dyed directly on acetyl silk, chiefly yellows, oranges and some reds. Vat dyestuffs, including indigo and those of the algal and indanthrene class, which can be vatted without use of large quantities of caustic soda, are suitable for dyeing unsaponified acetyl silk, saponification during dyeing being inhibited by presence of ammonium salt. Remarkable affinity of cellulose acetate for aromatic amines and phenols suggests vast range of possibilities for developing azo dyestuffs by diazotizing on the fibre. J. F. BRIGGS, *Textile Colorist*, 5-22, 2500 w. MBB.

Dyeing Viscose Silk. Artificial silk other capable of being dyed at low temperature. Bleaching may be done with weak solution of chloride of lime. Viscose artificial silk usually dyed with direct cotton dyes. Bath made up with reduction in amount of liquor. From 5% to 20% of the weight of fibre is added in form of Glauber's salt. Temperature maintained at about 120° to 140° F. Soluble oil often put into dyebath for purpose of facilitating evenness of dyeing. Many basic dyes may also be employed to dye artificial silk. Likewise acid dyes may be used, though fastness against washing cannot be expected from their use. GEORGE EMMON, *Silk*, 13-14-22, 1111H.

Textile *Books for Executives*

HERE are the titles of books which every administrator and department head of a textile business should have in his library—available for quick reference. These few titles are indicative of the high grade character of technical and general books which can be secured promptly through the INDUSTRIAL DIGEST. Address the *Book Department* for books on any industrial subject. There are thousands to select from. Our Book Department will gladly advise you which books are best suited for your purpose.

TEXTILE DESIGN, by Woodhouse and Milne.

Thorough description of every type of textile fabric, beginning with the plain weave and going through ply fabrics, pile fabrics to silk picture designs and fabrics. 500 pp.; 307 illustrations; 1400 different designs. \$5, postpaid.

COST CONTROL AND ACCOUNTING FOR TEXTILE MILLS, by Eugene Szepesi.

Covers complete information—data, forms and methods—regarding modern practice in textile mill cost control and accounting. Applicable to every class of textile mill, with special consideration of mills requiring extraordinary treatment. 450 pp.; 163 forms; flexible leather binding. \$10, postpaid.

CALCULATIONS IN YARNS AND FABRICS, by Fred Bradbury.

Covers woolen, worsted, cotton, flax, jute and silk yarns and fabrics; analysis and reproduction of woven fabrics and costing of yarns and weight and cost of fabrics are stressed. Valuable reference authority for the mill man. \$3, postpaid.

THE TEXTILE FIBRES, by J. M. Matthews.

A systematic account of the

physical, chemical and microscopical properties of the textile fibres. Third Edition. 630 pp. and 141 fig. \$5, postpaid.

STANDARD CLOTHS, by Robert Beaumont.

Structure and manufacture of standard cloths used for general, military and naval purposes: a very complete work. 342 pp. \$6, postpaid.

DYEING AND CLEANING OF TEXTILE FABRICS, by Owen and Standage.

Gives a list of dyes; recipes for dyeing wool, cotton and silk; preparation of cleaning liquors; removing spots and stains from garments; washing of silk, cotton and flannel and other woolen articles, etc. 120 pp. \$1.35, postpaid.

BLEACHING AND RELATED PROCESSES, by J. M. Matthews.

Invaluable to the textile chemist, the practical bleacher, responsible Mill Executives and manufacturers of bleaching materials: an authoritative treatise. 700 pp., 300 illus. \$8, postpaid.

TEXTILE SOAPS AND OILS, by Hurst and Simmons.

A handbook on the preparation, properties and analyses of the

soaps and oils used in textile manufacturing, dyeing and printing. 204 pp. \$4, postpaid.

COTTON SPINNING (3 vols.), by Taggart.

Complete reference work on cotton spinning. Vol. I includes all processes and machinery through carding. Complete calculations. 216 pp; 114 illustrations. Vol. II includes all processes and machinery of drawing, combing and fly frames. Complete calculations. 200 pp.; 84 illustrations. No. 3 includes ring and mule spinning; doubling, humidity, etc. Complete calculations. 435 pp.; 86 illustrations. \$10.80, postpaid.

WOOLEN AND WORSTED, by Robert Beaumont.

The manufacture of woolen, worsted and union yarns and fabrics in one large volume, from raw material to finished fabric. 755 pp.; 500 illustrations; 56 plates. \$10, postpaid.

SILK MANUFACTURING AND ITS PROBLEMS, by Chittick.

A cyclopedia for men in the silk manufacturing, dyeing and finishing business, covering problems from selection of mill site to marketing the product. 500 pp. \$2.50, postpaid.

Book Department, INDUSTRIAL DIGEST

25 West 45th Street, New York City

Time To Invest Abroad

(From page 1132)

prospect of such return as an experienced man ought to be able to get for his money. He knows there are plenty of good propositions looking for capital, if he could only find them and if he only had some way of making certain that those he finds are really sound.

There is one agency to which business men in the past have not been in the habit of referring for investment information, but which seems well equipped to give such service. This is the certified public accountant.

A number of accountants in the past few years have undertaken the task of investigation investment opportunities for their clients. This work has come to them as an incident of their regular accounting practice, and the fact that more money than usual is now seeking investment has occasioned the enlargement of their business. Some of them are now going so far as to establish "capital promotion departments," the function of which is to unite, on a sound basis, the investor and the seeker of funds.

"I believe that this sort of service is going to become one of the most important branches of the accountant's work," said M. L. Seidman, of Seidman & Seidman, a New York firm of certified public accountants. "We are an investigating profession, and therefore especially fitted to perform such duties.

"We find that a great many of our clients are looking for good investments, and in the course of our work we also run into many businesses which need capital. It is the most natural thing in the world for us to bring the two together.

"Certified public accountants cannot, of course, be brokers. They are members of a carefully supervised profession, with professional reputations to sustain. They should not, and indeed they cannot properly, charge commissions for capital promotion work. Their function is merely to investigate propositions for the business man who wishes to invest, and to lay all the facts before him.

"It is no easy matter to find a suitable investment for a business man with surplus capital. There is an unlimited supply of propositions, and an almost equally large supply of capital, but not all of the business seeking funds will stand the tests that a certified public accountant must apply to them, and sometimes those which pass the tests are not suited to the particular investor whom the accountant has in mind.

"A certain client of ours with several hundred thousand dollars which he cannot use in his own business has been looking for many months for something to put the money into. We have been looking, too, but we have not found the right thing yet. Surprising, isn't it, that so much money should go begging? But in the end I believe our client will get what he wants. We are now investigating several propositions for him, and we will give him the facts of these cases. We won't tell him what to buy, or what not to buy, but we will show him just what is what, and our professional reputations will stand behind our report. And I think that he will do better with the aid of such service than he would have done without it."

Oil from Canada

(From page 1137)

to Canada's 288,760. This production is reported by the Government geologists to be from the crest of a dome of the Delaware limestone (coniferous), at depths of about 300 ft. This productive field was developed from an abandoned prospect as a result of careful study of structural formations followed by practical drilling, it is quoted as proof that the possibilities of the Ontario oil fields are far from exhausted.

In New Brunswick and Nova Scotia oil possibilities have attracted attention since 1859, but competition with the enormous output of the adjacent United States oil fields has done much to discourage production.

New England's Cotton Mills

(From page 1127)

over which neither the manufacturer nor the most enlightened arbitrator has any control."

And the *Textile World*, an organ of the trade, said editorially:

"We can sympathize with the desire of industrial operatives to retain their comparative luxuries, but their refusal to bear their fair share of the enforced reduction in production costs and to endeavor to reduce their wage losses by longer and harder work will cost them the sympathy of a fair-minded public.

"Mighty few mills, business firms, executives or stockholders can show gross income today 75% to 80% higher than that of 1914, yet that is the wage advance that will be retained by New England textile operatives after the latest wage revision has become effective. Furthermore, in certain mills where weekly working hours have been increased, a large proportion of the most efficient workers are actually earning more than they were before the 20% wage cut was made," since they are paid by the hour.

With both sides thus standing firm, the strike dragged on and on. It began on January 24 with the closing of four mills in Pawtucket, R. I., and within a few weeks spread farther in Rhode Island. On February 13 it spread to Manchester, N. H., and in March it reached the Lawrence district of Massachusetts. In the beginning of June several mills attempted to reopen, feeling that the endurance of the operatives must be waning. Only a few workers appeared on the job at first, but the mills declared that the number was steadily increasing. By the middle of June the impression was abroad in the trade that the backbone of the strike had been broken, although few struck mills were carrying on any sort of extensive operations.

According to figures compiled by the *Daily News Record*, brought up to date on June 17, the number of spindles idle were 2,764,130; looms, 79,934; operatives, 50,763. The closed mills have a total daily capacity of 2,396,211 yards, and the total lost production up to and including June 17 amounted to 226,482,479 yards.

What does the future hold for the New England textile manufacturers?

There can be no question that they are in an extremely difficult position. Even if they are able, in the present instance, to enforce their wage reductions, their situation will be none too comfortable. The wages they can pay do not compare favorably with those paid by other industries in the North. The union in this strike is showing fully as great strength as it has ever shown before, and some think it is stronger than ever. Surely the labor troubles of the mill men will not be over after this strike. As Mr. Harris pointed out, the advantage of the South in this respect is great. Added to the advantage of proximity to raw materials, it is likely to be overwhelming.

A man who has followed the textile industry closely for many years expressed this opinion of its future:

"Capital invested in cotton mills will probably transfer itself by degrees to the South. A textile plant involves a tremendous investment in structure and equipment, and therefore the change in location cannot be sudden. Mill owners will put up a strenuous fight before they will abandon their property in the North. They will probably refuse to build new mills, however, and as the old mills get played out move their capital below the Mason-Dixon line. This is being done to some extent already. There is undoubtedly much Northern capital in the Southern textile mills today.

"The speed and completeness with which this change takes place will depend upon many factors, including the demand for cotton goods. If the industry experiences again such a clamor for cloth that the less economical mills can survive, then the North may continue for many decades as a leading textile center. But if competition is keen, the process of elimination may be faster than the Northern mill owners expect."

List of Magazines Digested

THE following selected list comprises nearly every leading trade and technical periodical in this country. The most important and informative articles (exclusive of matter bearing only a temporary or local interest) are carefully digested by our editorial staff and classified according to industry. Where an article relates indirectly to additional industries a reference will be found on the page devoted to each related industry.

The letter following the name of the publication denotes the period of issue thus: W., Weekly; S-M., Semi-Monthly; M., Monthly; S-A., Semi-Annually.

The figure denoting the annual subscription rate is followed by the single copy price. For the convenience of those who desire to subscribe to the various publications or to purchase special numbers, the address is given in every case. Constant additions to this list will be made as fast as practicable, and the editors will appreciate suggestions from our readers in regard to publications which, in their opinion, should be included in the magazines covered by The INDUSTRIAL DIGEST.

How Can You **Maintain Profits With Rising Production Costs ?**

The book, "Essentials of Industrial Costing," points the way. It tells of tried and proved methods by which the cost of production is derived, and shows how the most advanced industrial leaders keep their manufacturing costs down to minimum, chiefly by reason of their knowing the correct way to figure all the elements of costs, based on sound principles. This book, written by George S. Armstrong, should be read by every business executive now beset by falling profits on the one hand and stubbornly steady production costs on the other. This, and thousands of other equally good books, can be obtained from The Industrial Digest. "Essentials of Industrial Costing" costs only \$5, postpaid. It contains 297 pp. of valuable facts.

Book Department, INDUSTRIAL DIGEST

25 West 45th Street, New York City

A Master Key to the News of Business

OUT of all the flood of information that pours in on you through newspapers, trade papers, magazines and other sources, how are you to sort out the pertinent facts that bear on your business? Wouldn't a master key to the news of business be worth (literally) its weight in gold to you?

THE INDUSTRIAL DIGEST is precisely such a service. Out of all the news of the daily press, the trade and business press and all other sources, it selects, verifies, evaluates and arranges the business facts of importance and sets them forth digested and indexed—and interestingly presented.

THE INDUSTRIAL DIGEST presents the business fortnight in perspective. It offers the major executive in every field of business the opportunity to keep himself acquainted, with a minimum of attention, with important events in his own industry and in other fields of business as they bear on his own.

IT costs tens of thousands of dollars a year to prepare THE INDUSTRIAL DIGEST. But the subscription price to each executive is only five dollars a year.

This coupon will bring the service to you once every two weeks for one year.

THE INDUSTRIAL DIGEST,
25 West 45th St.,
New York City.

Please send your fortnightly survey of American industry and commerce to me for one year. I enclose five dollars, check or money order.

INDUSTRIAL CALENDAR

Secretaries of Associations are invited to send us the dates of their conventions as early as possible so that their conventions may be properly listed below. When especially requested by Association Secretaries, we will send dates and other available notices concerning meetings of other associations.

- June 26-27. *National Ornamental Glass Mfrs. Assn.*, Cincinnati, O. (C. C. Jacoby, Secretary, 2700 St. Vincent Ave., St. Louis, Mo.)
- June 26-30. *American Institute of Electrical Engineers*, Niagara Falls, Ont. (29 W. 39th St., New York City.)
- June 26-July 1. *American Society for Testing Materials*, Chalfonte-Haddon Hall Hotel, Atlantic City, N. J. (C. L. Warwick, Secretary, 1315 Spruce St., Philadelphia.)
- June 27-29. *Canadian Assn. of Stationary Engineers*, Kitchener, Ontario. (G. C. Keith, 51 Wellington St., West, Toronto, Ontario.)
- June 28-29. *American Association of General Baggage Agents*, Minneapolis, Minn. (E. L. Duncan, 332 South Michigan Ave., Chicago, Ill.)
- July 9-12. *International Association, Display Men*, Chicago, Ill. (L. A. Rogers, Secretary, John D. Mabley Co., Detroit, Mich.)
- July 10-15. *Export & Import Exposition*, Baltimore, Md. (A. E. MacKinnon, 405 Lexington Ave., New York.)
- July 12-14. *National Assn. of Stationary Engineers*, Springfield, Mass. (James Morgan, 53 Devonshire St., Boston, Mass.)
- July 16. *American Institute of Banking*, Portland, Ore. (R. W. Hill, Secretary, 5 Nassau St., New York.)
- July 19-21. *National Assn. of Stationary Engineers*, Kalamazoo, Mich. (A. M. Adams, 1307 Stockbridge Ave., Kalamazoo, Mich.)
- July 25-28. *National Retail Tea & Coffee Merchants Assn.*, Hotel Statler, Detroit, Mich. (R. M. Heizer, Secretary, 1201 Cornell Ave., Indianapolis, Ind.)
- Aug. 23-25. *American Association of Railroad Superintendents*, Kansas City, Mo. (J. Rothschild, 400 Union Station, St. Louis, Mo.)
- Aug. 28-Sept. 2. *National Safety Council*, Detroit, Mich. (S. J. Williams, Sec., 168 N. Michigan Ave., Chicago, Ill.)
- Sept. 4-9. *Gas and Fuel Section of the American Chemical Society*, Pittsburgh, Pa. (Dr. R. S. McBride, Secretary, Colorado Bldg., Washington, D.C.)
- Sept. 11-15. *Association of Iron and Steel Electrical Engineers*, Cleveland. (J. F. Kelly, Secretary, Empire Bldg., Pittsburgh.)
- Sept. 11-16. *Bakery Equipment and Material Exposition*, Municipal Pier, Chicago, Ill. (B. M. Warner, Secretary, Conway Bldg., Chicago, Ill.)
- Sept. 12-14. *Retail Bakers of America*, Chicago. (J. M. Hartley, Secretary, 10 S. La Salle St., Chicago.)
- Sept. 12-15. *American Bakers Assn.*, Chicago. (H. E. Barnard, Secretary, 1135 Fulliton Ave., Chicago, Ill.)
- Sept. 25-29. *National Association Retail Druggists*, Detroit, Mich. (S. C. Henry, Secretary, 168 N. Mich Blvd., Chicago, Ill.)
- Sept. 25-30. *National Association Advertising Specialty Mfrs.*, Chicago, Ill. (B. Blackwood, Secretary, 208 S. LaSalle St., Chicago, Ill.)
- Oct. *American Electric Railway Association*, Chicago, Ill. (J. W. Welsh, 8 West 40th St., New York.)
- Oct. 2-6. *American Bankers Association*, Hotel Commodore, New York. (W. G. Fitzwilson, Secretary, 5 Nassau St., New York City.)
- Oct. 2-7. *American Society for Steel Treating, International Steel Convention*, General Motors Bldg., Detroit, Mich. (W. H. Eisenman, Secretary, 4600 Prospect Ave., Cleveland, Ohio.)
- Oct. 11. *National Association Electrical Contractors and Dir.*, Cincinnati, Ohio. (W. H. Morton, Secretary, 15 W. 37th St., N. Y. C.)
- Oct. 11-13. *National Federation of Implement Dealers' Association*, Chicago, Ill. (H. J. Hodge, Secretary, Abilene, Kan.)
- Oct. 11-14. *Pacific Coast Logging Congress*, Tacoma, Wash.
- Oct. 17-19. *American Railway Bridge and Building Association*, Cincinnati, Ohio. (C. R. Lichty, Chicago & North Western Ry., 219 North Waller Ave., Chicago, Ill.)
- Oct. 18-20. *National Association Farm Equipment Mfrs.*, Chicago, Ill.

Foreign Events

- June to November. *French Colonial Products*, Marseilles, France.
- June 24-Sept. 15. *Annual Exhibition of Ceramics and Glassware*, Dresden, Germany.
- July. *Second Near East Sample Fair*. New exposition buildings being erected along the Danube.
- July 1-24. *Aircraft Exhibition*, London, England.
- July 9. *Universal Exhibition*, Buenos Aires, Argentina.
- July 24-29. *International Tobacco Trade Exhibition and Conference*, London, England.
- Aug. *Second Sample Fair*, Lublyana (Leibach), Yugoslavia.
- Aug. 12-20. *Third Annual Sample Fair*, Liberee (Reichenberg), Czechoslovakia.
- Aug. 27-Sept. 2. *Autumn Fair*, Leipzig, Germany.
- Sept. *International Exposition (centennial)*, Rio de Janeiro, Brazil.
- Sept. 15. *International Fair*, Bandoeng (Java).
- Sept. 18-23. *International Chamber of Commerce*, Rome, Italy.
- Sept. 21. *Textile Fair*, Hamburg, Germany.
- Sept. 25-Oct. 3. *Automobile Show* at the Kaiserdamm Hall, Berlin, Germany.
- Oct. 1-15. *General International*, Lyons.
- Oct. 4-15. *Automobile Show*, Grand Palais, Paris, France.
- Oct. 12-23. *International Commercial Vehicle Exhibition* at Olympia, London, England.

SEDGWICK

.... and when you're in a hurry

WHERE speed is of the essence, where lifting and lowering equipment must quickly be procured, call upon Sedgwick.

Thirty years' experience has shown us what type of Hand Power Elevator, Dumbwaiter or Gravity Lift you are most likely to need, and chances are we have it in stock ready for immediate shipment.

In addition to those models which we carry in stock, our files hold the designs for hundreds of special machines. Obviously it requires the shortest possible time to manufacture machines from plans already drawn.

Our long experience exclusively in the Hand Power Lifting and Lowering field insures that installation, as well as construction, shall be done with utmost expedition.

Write and ask us to prove we can help with your lifting and lowering problems.

For lifting
and lowering —
SEDGWICK

In the same way, if you already have a Sedgwick machine, you can get it repaired or have it replaced with a new one. Write Sedgwick Hand Power Elevators and Dumbwaiters, Inc., for literature and prices.

SEDGWICK MACHINE WORKS

For 30 Years Manufacturers Exclusively of Hand Power and Gravity Lifting and Lowering Equipment

150 WEST 15TH STREET, DEPT. D, NEW YORK, N. Y.

THE SCOOP CONVEYOR

*Cuts Cost of Loading
and Unloading*

WHEN unloading hopper bottom cars, the "Scoop" end of the conveyor is placed directly under the hopper of the car and the belt carries the coal away as fast as it flows through the car hopper. In this way a 50 ton car can be unloaded in one hour. No pit or track hopper is needed and cars can be unloaded at any point along the track.

When loading from piles the "Scoop" end is pushed or buried right into the pile, making it very easy for one man to scrape the coal onto the belt to its full capacity of a ton a minute.

For Storing, reclaiming or transferring; the most flexible kind of a conveying system can be built by using two or more of these machines in tandem style, one feeding the other. Each machine being complete in itself and easily portable, can be used separately at any time.

Over 5,000 Scoop Conveyors are in daily use. Write for catalog No. 51, showing how they reduce handling costs.

Portable Machinery Co.
Passaic, N. J.

The **INDUSTRIAL DIGEST**

What's Wrong With Our Coal Industry?

See page 1198

Do You Want A Basis For "Scientific Profit Making"?

Out of our long experience of the past, we have developed a fundamental service, which reconciles accounting and costing with sound industrial economics.

It is a service which will enable an Executive to more intelligently and efficiently operate the complex business machinery of his Concern.

This service is built around these elements—

- 1—Proportioning Profits to Complexity and Effort Expended in Producing Goods.
- 2—Determining Scientific Prices through consideration of Plant Capacity Factors.
- 3—Reconciling Differences between Market and Cost Values of Materials.
- 4—Eliminating Waste Factors from Direct Costs.
- 5—Separating Profits or Losses due to Volume and Purchasing, which are cyclical factors, from Operating, which is a yearly proposition reflecting the efficiency and economy of Manufacturing.

We can demonstrate to your satisfaction, the economic and commercial soundness of these five points.

Send for a specification of this service, a statement of the economies behind it and the results possible through its use; also a list of 14 questions, the answers to which will demonstrate to you whether you have a "scientific profit making" basis or not.

If the answers are "No," as many of them are likely to be, you NEED this service, and need it NOW.

We have yet to find a single case where all of the five points mentioned are in use.

Other services of importance to industry at this time are—

"Waste Elimination Week"

"Technical Savings Sharing"

May we tell you in person about our latest plans
for rendering counseling and advisory assistance?

Knoeppel
Organized Personal Service

C. E. KNOEPPEL & CO., Inc.

*Consulting
Industrial Engineers*

*Under Personal
Direction of Mr. Knoeppel*

52 VANDERBILT AVENUE, NEW YORK

Have you our Blue Book No. 3?

Economize *HERE—* *Not by WAGE-CUTTING!*

If you **must** reduce operating expenses, look around before you cut the wage scale and see if there are not some **other** places where you can effect economies. Are you **sure** there is no industrial waste in your plant? No leaks that **might** be stopped if you tried?

According to the findings of the Federal Engineering Societies, engineering **efficiency** could be approximately doubled by the adoption of the most approved methods.

Wherever you introduce methods of approved superiority you automatically **reduce production costs!**

Two striking examples of this principle are found in the Steam Trap Sarco and the Sarco Temperature Regulator.

The first, by enabling you to trap your steam lines at **numerous** points—where the steam is **used**—instead of at a **few** points, keeps the pipes free from condensate. This in turn permits the steam to maintain itself at maximum temperature, without the loss of heat units which invariably follows where condensate is forced to travel great distances before it reaches an outlet. Small and compact, the Steam Trap sells at about one-third the price of the cumbersome, heat-wasting bucket type trap—a price differential that makes it possible for you to trap your lines **thoroughly** and hence at greatest steam-economy.

In heat-treated processes, or where temperature control is required, the Sarco Temperature Regulator also has proved itself a factor in prevention of waste. Controlling temperatures accurately by reliable automatic means, this device does away with the guesswork which so often results in errors and costly spoilage.

In the whole range of plant equipment you will not find two more faithful allies in the war against waste than these scientifically designed, dependable accessories.

Don't Cut Wages! Cut down Steam Loss and material waste with the Steam Trap Sarco and the Sarco Temperature Regulator. Write today for descriptive booklets Nos. F-27 and F-68

“Open Sesame!”

ALI BABA murmured the magic words, the cavern door swung open and costly treasures lay at his feet.

You, too, have an “open sesame” to the treasures of the world. It is *advertising*.

Read the advertising and you open the door to countless comforts and conveniences you otherwise would miss. For advertising will spread before you the product of fields, looms and factories the world over—things that make life easier, happier, more interesting and more fruitful for you and your family.

There is no questioning the real benefits that come from regular and systematic reading of the advertising columns. No other one thing will give you such economy and keen satisfaction in buying.

Advertising is far too important to be overlooked.

Read it
It is a profitable practice

ANOTHER LEADER IN INDUSTRY

Endorses Estes Service

A. E. ALTENBERG President of the Icy-Hot
Bottle Company of Cincinnati says:

*Production
Increase—20%*

*Decrease in Labor
Turnover—20%*

*Breakage
Reduced—30%*

"In July, 1920, we had more orders than we could fill. In discussing our difficulties with another concern whose troubles had been similar to our own, they recommended L. V. ESTES INCORPORATED as being qualified to help us with our problem. So, we called them in, principally to assist in increasing production, but their help was more far-reaching than that, for besides increasing production 20%, they decreased labor turnover 20%, reduced breakage 30%, and assisted materially in other ways—and all this was accomplished in the short space of 4 months.

*Training Department
of Decided
Advantage*

"One development in particular, due to Estes' Service, meant much to us—and that was a training department where green men were taught to be skilled glass workers. This insured us of a steady supply of trained men. Formerly, when an expert glass worker became sick, we lost production, but after the training school had been installed, the expert's place was at least partially filled by one or two of the students.

*Close Contact
Between Estes
Organization and
Engineer*

"The Estes man was very diplomatic, and worked well with the Icy-Hot employees. The Estes Company kept in very close touch with the job, and their services were satisfactory."

A PART OF OUR SERVICE is to send an engineer to your plant to examine conditions that exist and consult with you as to the value of changes that might be made. This service is without charge to you—just write us that you would like to have it.

CHICAGO

The Business Weathervane

A Summary of Expert Opinion

"The status of general business has not changed much during the week, but evidence of further improvement is not lacking. Progress would be more rapid if labor troubles were not present in some important industries, yet gains this year have been substantial and the decidedly stronger fundamental conditions promise well for the future," says **Dun's Review**. "While competition for business is still keen in different lines, the initiative in most transactions is no longer with the seller, and pressure for deliveries has become sufficiently urgent in certain instances to result in premiums being established

on quick shipments. With advances predominating on **Dun's** list of wholesale quotations during 20 of the last 25 weeks, the reaction from previous price depression has clearly been decisive, and the prospect of higher levels to follow now influences the buying policy in some markets."

The important factor at the present time is the money rate, but opinion differs as to the probable future trend of money. According to the **United States Business Service**, "Money is a great governing factor behind a bull market, and at the moment the banking outlook holds no indication of any untoward circumstances which might force a tightening of money. Money conditions are excellent, and when easy money is to be found in conjunction with business recovery it should be a fair assumption that the stock market will not start its long downward trend until a point is reached where business makes a sufficiently heavy demand upon the money market to cause stocks to suffer through lack of available call funds in the call market. Call money today is very cheap, and interest rates are expected to continue downward during the summer, probably reaching their minimum low some time in September."

On the other hand, the **Times Annalist** points out: "There

is more evidence now of business expansion, and if this continues it is not unlikely that before long the demands of business may be felt to an increasing extent in the money market, with the result that rates may show something of a hardening tendency from now on. If money is to begin to flow into industrial activities, then it may be expected that the stock market will, as time goes on, feel the pinch for funds when there is any pronounced upturn in brokerage borrowings. In so far as car loadings are an index to business

recovery, the record for the week ended June 10 shows a decidedly encouraging situation. The total of 846,002 is an increase of 95,357 over the preceding week, and 58,719 over the corresponding week of 1921. The significant fact in connection with the loadings is that the total for the week of June 10 came within 33 cars of the largest loadings for any week this year. Also, it was worth while noting that the loadings of coal amounted to 94,824 cars, a figure which is larger than for any previous week since the coal strike started. If coal loadings were within range of normal, total loadings would reach a figure close to the high point of 1920."

According to the **National Industrial Conference Board**, "Business conditions continue to improve and the number of industries reporting betterment is greater than in previous months. In some instances orders placed show a decline.

Nevertheless, confidence generally continues and the feeling grows steadily that the country is at last beginning to emerge from the depression. The number of business failures shows an appreciable decline. In January, 1922, the number of failures was 2,723; in February, 2,331; in March, 2,463; in April, 2,167; and in May, 1,960. Wholesale prices have shown an upward trend. Retail food prices showed no change between April 15 and May 15, 1922. The studies of the Board indicate that the cost of living on May 15, 1922, was 54.9% above that in July, 1914."

Just as he was getting back to earth.

The Fortnight

The Herrin "Massacre"

HERRIN, ILL., has taken the prize for first honors in riot-and-murder settlement of labor disputes away from Mingo, W. Va. Those who undertake to explain the actions of a Herrin lynching mob do so on the grounds that this sort of violence is expected to terrify other "wrongdoers" to such an extent that they will not attempt to break the law. But there can be no such explanation in the case of the Herrin strikers, because there was no lawbreaking concerned. Nor was there any possibility that acts of violence such as were performed there could by any chance put the workers on better terms with the company than a hands-off policy. As one publication expressed it, union labor has stabbed itself and unless this sort of thing stops completely union labor may bleed to death. Public opinion will not stand for a repetition of the Herrin massacre, no matter who is to blame. Each side naturally blames its opponent for the trouble, and there could hardly be a crisis so acute as this without a good deal of blame for both parties to the conflict. Whatever the trouble, it should be settled once and for all.

The Railroad Strike

AS if to prove that union labor has not had its share of strikes in the last six months, along comes the railroad strike, which began on July 1. At this writing it is impossible to tell how far the trouble will develop, but it is impossible for the rail unions to gain anything by the strike at this time, according to most editors.

President Harding has made the statement that the Government would not permit the country to be hamstrung by a transportation tie-up at this time. This is interpreted in most circles to mean that vigorous action will be taken even to the extent of calling out troops to operate the roads and maintain order. The Government possesses the authority to do this under the Esch-Cummins bill.

The Coal Strike

THE United Mine Workers of America have made a proposal to the railroad brotherhoods to refrain from handling any coal from the mines. A sympathetic strike of this

sort could do great damage were it not for the fact that comparatively little effort is necessary to transport the coal now being mined, whereas it would be of considerable importance were such an agreement to go into effect when both union and non-union mines were operating. The railroads will not be hard put to it to handle non-union production. The Administration, confronted with the cold, hard fact that our coal reserves are being so rapidly depleted that another month will see industry in serious difficulty, is said to be preparing to force the coal strike issue to a settlement. It is stated that the railroads have less than 7,000,000

tons on hand, according to some estimates, against which they are drawing at the rate of 145,000 tons daily. In seven weeks this reserve will be wiped out. At a conference between President Harding and Secretary of Labor Davis and John L. Lewis, president of the United Mine Workers of America, the differences between the operators and miners were thoroughly discussed, as well as the fundamental situation in the bituminous industry. It is understood that three points were stressed. First, over-development of the industry with its excessive number of mining operations; second, the excessive number of men employed; third, the intermittency and inadequacy of employment for miners. The union leaders insist upon the following course, according to informed circles: First, the President shall set a date for a joint conference of coal operators and miners' officials. This conference will sit until it terminates the present situation. Once the present strike is disposed of Congress would pass legislation creating a commission with full power to

subpoena witnesses and records of both sides to the end of making an investigation, and getting down to the fundamentals of the problem. It is understood that the Administration favors the appointment of a commission of this character somewhat along the lines of the Interstate Commerce Commission.

Operators state that they will decline national treatment if possible, and insist on settlements by States, for one reason because not otherwise can they avoid the risk of prosecution under the anti-trust laws. They are considering, also, the opening up of mines in union territory with non-union labor.

(Philadelphia North American)

Too Tough a Proposition Even for a Lifeguard

in which case they will ask for protection by injunction under the Coronado decision.

The Textile Tie-up

THE textile strike in New England continues at a deadlock and production is being hampered to such an extent that prices may be materially affected this fall. With the coal industry, the railroads and the textile industries all hampered by strikes, it would seem that the time had come for union labor to "step on the soft pedal," according to editors of various trade and technical publications.

The Tariff and the Senate

THE Senate has been dawdling along with the tariff schedule and at the present rate no doubt it will be enacted before the next Presidential election. Business men all over the country are clamoring for immediate definite action on the bill and still Congress is playing politics. The Administration, faced with a party split on the tariff, is anxious for a scientific solution somewhat along the lines of the Freylinghuysen amendment, but nothing of this sort is possible at the current session. The majority of newspaper opinion is to the effect that there will be no tariff enacted at this session. On the other hand, keen observers in the Capitol insist that the bill will be passed if only to give the Democratic party a chance to use it as capital at the polls in November. There has been a great deal of dickering going on over the schedules, and many of them will be modified before the bill goes through.

Perhaps some indication of how dangerous the tariff bill is supposed to be as a party measure may best be gained by considering the effect on its two sponsors. Neither Senator McCumber nor Representative Fordney will be in Congress next session, the former having been defeated in the primaries in North Dakota and the latter having declined to run for re-election. There is no doubt but that the tariff bill is loaded with too many high schedules, and if it passes its effect on the party in power will not be wholesome.

Business Looking Up

THE industrial situation has been improving steadily and at the present time indications are that though the summer will be quiet, the fall will be very active. Railroad car loadings have increased materially and the number of idle cars has decreased. A number of automobile companies have broken all previous records for production and sales. Within the last few months the steel industry has passed from a condition of relative inaction to one in which business is being placed for the third quarter of the year. As a result prices are turning upward and leading publications in the steel industry agree on the favorable condition of the industry and admit that the only factor which may tend to cause difficulty is the coal strike, and that even this is not likely to slow up production materially.

Secretary of Labor Davis has announced that unemployment has been steadily eliminated in the East and considerably reduced all over the country. The discount rates of the Federal Reserve Bank have been reduced, foreign exchange is displaying unusual strength, and in general financial conditions have been very favorable to industrial activity.

Coronado Decision Causing a Stir

THE famous Coronado decision of the United States Supreme Court, to the effect that unions are suable, is apparently one of the most important decisions that have been made for a long time. Not only will additions to this decision be numerous, but such important disputes as the rail strike and the coal strike may be hastened to a settlement on account of this decision. In addition, labor leaders hold that since labor unions can be sued they can also sue, and counter actions are expected under the new ruling.

Now comes word that the organized farm movement which has been growing in the United States at an astonishing rate during the last few years feels that the Coronado decision is equally menacing to it. Members of the farm bloc who have studied the decision have admitted that they could see no reason why the court's decision is not applicable to the farmer's co-operative movement.

There Is, Indeed, a Relation Between Coal and Other Industries

What's Wrong With Our Coal Mining Industry?

Why does most of our serious industrial trouble center around the mines—and what can be done to correct conditions so that the present disastrous strike may not be repeated next year?

WHY does murder go hand in hand with coal mining in this country? Why do riots repeatedly convulse our coal industry? Why, every once in a while, does an army of strikers march upon coal-mine property, shooting sheriffs, guards and strikebreakers, being fired upon in return? Why is there bloody warfare in the mining districts more often than in any other industrial center?

Surely there is something seriously wrong in an industry that runs amuck so often. Civil wars and massacres in West Virginia and southern Illinois could not take place if beneath-the-surface conditions were not fundamentally bad.

What is wrong with the coal industry? What can be done to correct the evils? No one can give positive answers to these questions, but it is time somebody tried to find them. The importance of coal to the entire industrial life of the country cannot be overestimated. Coal is the heart of American industry—and industry cannot afford heart trouble.

THE INDUSTRIAL DIGEST cannot answer the questions raised by the trouble in the coal industry, which was fastened upon public attention by the massacre at Herrin, Ill. It can only point out a few facts that seem pertinent, and present opinions of public organs and persons in touch with the situation.

The event at Herrin was one of the most sensational strike riots that has occurred in recent years. A party of strikers marched upon a strip mine operated by the Southern Illinois Coal Co., captured the mine superintendent and a party of workers, marched them off and massacred about 40 of them. For the next two or three days the bodies of victims who had been shot or beaten to death were picked up in roads and fields around Herrin, and fished out of ponds. Surviving strikebreakers told horrifying stories of cruelty.

Each party to the immediate controversy that led to the massacre blamed the trouble on the perversity of its opponent. Officials of the Southern Illinois Coal Co. blamed a telegram sent by John L. Lewis, president of the United Mine Workers of America, to the local strike leaders, saying that "representatives of our organization are justified in treating this crowd (the strikebreakers) as an outlaw organization." Union officials blamed the coal company, saying that it had violated an agreement when it tried to work the mine with non-union men, and that it surreptitiously armed the mine guards. Most newspapers attribute the massacre to sheer murderousness.

"It is for Americans outside of Williamson County and outside the sacred supra-legal circle of the union to ponder

this arch-deed of savagery," says the *New York Times*. "Is the law of the statute books or tumultuary violence, executing the will of the labor union, to prevail? At the moment when a strike to paralyze the communications of the country is blithely promoted, consideration of the rights of all as against the usurpations of a class, of law for all against the lawbreaking of a class, is especially needed. 'Ordered freedom under the law—' what a fine, sonorous phrase! In Williamson County and, from time to time, in many other parts of the country, it is nothing but a phrase, an irony, a cruel joke. It was fortunate that the United States didn't accept a mandate for Armenia. Our own massacres will keep us more than busy."

The *St. Louis Globe-Democrat* echoes a universal sentiment when it says:

"No purpose of organized labor has been or can be advanced by such a grievous and misguided form of resistance as that employed at Herrin. The blood of blameless men, whose only offense was that they accepted employment of which they were in need to earn their bread, cries out against the cause in which they came to their death."

But the cry of "murder" is useless after the damage has been done, and as the *New York World* remarks:

"It is a waste of words to discuss the firing of the first shot or even the cause of the strike, as if settling the responsibility would bring the matter closer to a solution."

"As the shooting at Herrin was an incident in the strike, the strike itself is an incident in the history of inefficiency

(© International)

and unrest in the coal mines. Bituminous mining in the United States hardly deserves the name of a business. It is a chaos, and a bloody one. Because of seasonal production and uneven demand there are nearly twice as many men in mining villages as are needed. Because there are too many for the jobs on hand, and because they are isolated from communities that might furnish other employment, the miners cannot enforce their demands under normal conditions. With surplus labor keeping wages low, the pits will show a profit in a good year even when run without modern machinery or without regard for scientific engineering methods.

"They are so run, and according to the Federal Trade Commission they do show a fair profit. At the same time, a majority of the men are poorly paid upon an annual income basis and often desperate. When they strike they are met by the solid facts that there isn't enough money for higher wages, that there aren't enough orders to run more than 60% of the mines. They are met also by the autocracy of the mine-guard system, established to handle desperate employees."

"There is no final solution except a complete reorganization of bituminous production. Until that is done it will be necessary to restrain both sides from violence in a dreary series of conflicts ever menacing civil warfare. One after another, strikes will recur, bringing violence with them if continued, so long as coal is mined in this country as it is mined now."

* * *

One of the salient characteristics of the present method of bituminous mining is the unevenness of production. Mines open and close spasmodically. Irregularity, to the mine oper-

ators, means increased costs, lower profits, difficulty in obtaining and keeping an adequate force, mechanical troubles in the mine and waste of the resources. More important as an explanation of warlike conditions are its effects upon the workers.

"The potential working year in the American bituminous industry is 308 days," says F. G. Tryon and W. F. McKinney of the U. S. Geological Survey, writing in the *Survey Graphic*. "In the last 30 years the mines have actually worked on the average 215 days, and have lost 93 days, or 30% of the potential time in enforced idleness due to one cause or another. Even during the war, with an intense demand for coal and a working force depleted by the draft, the days lost numbered 65 in 1917 and 59 in 1918. In no other year before or since has the loss been less than 74 days, and in dull times it has frequently risen to 110 days. In 1919 the loss was 113 days; in 1920, at least 84 days; and in the disastrous year 1921 the industry as a whole probably lost 139 days, or more than after the financial panic of 1893.

"The burden of this loss falls heavily upon all who are concerned in mining coal or in transporting it, and, though unseen, it rests heavily upon those who use coal.

"The consequences to the miner are the most obvious. To him the short working year is a direct loss of income. It drives him to demand a daily rate of return that will compensate for the days when he cannot work."

The fundamental fact at the bottom of this is that America's bituminous mines are developed to an annual capacity of 750,000,000 tons, when the most that has ever been burned or

exported in a year is estimated to be about 550,000,000 tons.

An additional cause of mine idleness is the constantly accruing car shortage that plays havoc with fuel transportation. It is estimated that the mines can load about 15,000,000 tons on cars a week. The maximum weekly capacity of the railroads is 12,000,000 tons—sufficient to handle the maximum yearly capacity of the mines if offered to them in equal weekly instalments, but not enough to take care of the maximum weekly mine output. When the demand for coal is active all mines seek to enter the market and all ask for cars to the limit of their rating. Hence the shortages of cars, which are due, not to a real lack of transportation facilities, but to irregularity of production.

"No doubt we need more cars, but simply increasing transportation facilities will not mend the broken year of the coal miner," says Tryon and McKinney. "The principal beneficiary will be the consumer of coal. Ample transportation is his

best protection if he is to continue his present luxurious habit of buying coal whenever he wants it, without reference to the ease of supplying it. More cars, however, will not sell more coal. They will merely affect the distribution of working time through the year, tending to increase it in the periods of peak demand, and to make it still less than now in periods of low demand. Car shortages have occurred not infrequently, but it is a curious fact that rarely have they curtailed the actual consumption of coal. For the most part their effect has been to limit the quantity produced in the fall and winter, thereby forcing purchases to be made earlier in the year.

Living quarters erected by West Virginia strikers who have been "out" since April. The bitterness of the struggle is emphasized by scenes such as this. (© Underwood)

"Transportation as the primary cause of the short working year in coal mines must therefore be dismissed. Its effect is secondary rather, and consists in controlling the distribution of work from season to season.

"Much the same is true of that part of mine idleness attributable to labor. Losses due to strikes are spectacular when they occur, and in the last 20 years have mounted up to the enormous total of 125,000,000 man-days. But the time lost on account of strikes is only 10% of the total time lost (or 3% of the year's working time), and it may be questioned whether much more coal would have been produced in the aggregate during that 20-year period if there had been no strikes. The strike of 1919 did force consumers to go without coal for a brief period, and was an underlying cause of the scarcity in 1920, but the complicating factors at that time were exceptional. More commonly strikes have been discounted in advance by accumulating large reserves of storage coal, and the task of meeting the country's requirements has been shifted to other mines or to other periods of the year not affected by the strike. In terms of man-days lost because of strikes, the year 1910 was the record. If seasonal demand is to be overcome, it can be only by storing an additional 21,000,000 tons in the dull season. To accommodate this tonnage above that ordinarily carried in stock presents difficulties, but they are not insurmountable, provided storage can be made financially attractive to the consumer. Various devices looking to that end have been proposed, among them seasonal freight rates and summer discounts in prices.

"There remains a measure of idleness which must be ascribed to sheer overdevelopment beyond even the maximum season's requirements. Allowing 44 days of idleness on account of seasonal demand, the loss due to overdevelopment may be placed at 34 days, but its share would increase if seasonal demand were eliminated. Smoothing out the demand into equal monthly instalments would not increase the total demand nor decrease the total capacity. It would change neither the number of days worked nor the number idle. Its effect would be merely to transfer 44 lost days from one ledger account to another. Eliminate seasonal demand and it would be necessary to debit sheer overdevelopment with a loss of 34 days plus 44 days, or a total of 78 days."

Much of the trouble in the coal mines is undoubtedly attributable to this overdevelopment, and the consequent interruption of operation. But other industries also work intermittently. There must be something more about coal mining which induces riotousness.

Perhaps the very nature of the work is partly responsible. Labor in a coal mine is not conducive to gentleness of spirit. Those of us who can toil above ground cannot realize just

what digging coal out of a mine means to the worker.

Such a life makes men hard, stubborn, and willing to fight for what they think—rightly or wrongly—they must have. Coupled with these difficult working environments, hard living conditions are often found. This is especially true in West Virginia.

During the Mingo uprising last year much was published in the newspapers about the condition of civilization in West Virginia that is responsible for the repeated battles between miners and operators. The newspaper correspondents found that life in coal fields shed considerable light upon the violence of the struggle.

"If you will take a map of West Virginia, you will see that it is much like the map of any other State," wrote Winthrop D. Lane in the *New York Evening Post*. "Deep ridges of hills cut across its eastern and southwestern portions, but aside from these there is little to distinguish it from other maps. The same winding lines indicate rivers, the same dots show where its towns are, the same network of railways connects these dots.

"One can easily imagine the life that goes on in these towns as being the same that goes on in small towns everywhere. He can imagine people owning their own homes, pursuing a variety of occupations, attending to their own little affairs, and sharing in the town's common activities. He can imagine them acting like the independent citizens of other communities.

"But he will be mistaken. Nothing of the sort goes on there. In the coal-mining fields of West Virginia, comprising parts or all of 36 counties, the dots on the map do not stand for towns in the ordinary sense. They stand for clusters of houses around a coal mine.

"They do not indicate places where people lead an inter-related, many-sided and mutually dependent existence. They indicate points at which seams of coal have been opened, tipplers erected, and coal has been brought forth as fuel.

"True, people live here, but they live here to work. The communities exist for the coal mines. They are the adjuncts and necessary conveniences of an industry. They are not independent groups of people. They are not even called towns in the language of the locality. They are called 'camps.'

"No one owns his own house. No one conducts a store, runs a garage, sells groceries or furniture to his fellow townsmen, or amuses them in a movie theatre. No one is free to decide today that he will change his occupation tomorrow, because there is no other occupation than coal mining; the only way he can change his occupation is to move to some other region.

What the Press Thinks of the Herrin Massacre

Is Your Coal Bin Empty Yet?

Have you anticipated the coming coal famine, or will your plant starve to death on account of lack of fuel?

AS the coal strike drags on, the nation's reserve supply of fuel is rapidly diminishing. At the present rate of consumption and production the danger point will be reached within a month, according to estimates compiled from reports of the United States Geological Survey and the Department of Commerce. If production is not increased by that time, it is said, the factories of the nation will have to shut down for a day or two each week to conserve the supply.

Manufacturers in New Jersey, according to reports of the employment service of the Department of Labor, have already begun to feel the pinch, and have been forced to curtail their activities to some extent.

Since April 1 the anthracite mines of the country have produced only a few thousand tons of coal. During that period they usually mine about 20,000,000 tons, nearly one quarter of the entire year's requirements. They are so far behind now that if work in the anthracite regions were to start tomorrow it would be impossible to turn out a full supply this year, even if the mines operated constantly at maximum speed, and had a continuous supply of all the freight cars they needed to take the fuel away.

In the bituminous industry the non-union mines are running at a terrific rate, producing between 5,000,000 and 6,000,000 tons a week. One Wednesday in the middle of June they broke a record by producing more than 17,000 carloads—the largest single day's production ever turned out in those fields. But in spite of the best they can do the nation's weekly consumption exceeds production by about 2,500,000 tons.

The situation in the bituminous industry, according to Government reports, has never been paralleled before. With the certainty of a shortage before them, the consumers of soft coal nevertheless delayed their purchases until the new freight rates went into effect on July 1. Up to that time coal accumulated at terminal points, clogging up transportation facilities.

In Alabama, at the close of June, there was so much non-union coal on hand that the bottom dropped out of the market. An order by the Interstate Commerce Commission permitting Alabama coal to travel into the Chicago market at a competitive freight rate with West Virginia coal brought thousands of tons north from Alabama, but left the Birmingham market still overloaded.

Now that the rates have been reduced a heavy demand is expected. New England, which has been holding off, will probably put its orders in, and the rest of the nation will do

likewise. Then the shortage will begin to be apparent in the market.

Meanwhile the Federal Government lets it be known that it is taking measures to end the strike. The President's first efforts to effect a truce were unsuccessful, in spite of protracted conferences between John L. Lewis, president of the United Mine Workers, and members of the Cabinet.

Later, however, more optimistic reports came from Washington. It was announced that through the intervention of Mr. Lewis the anthracite leaders at Wilkes-Barre had abandoned all plans to turn the present "suspension of work" into a real strike. The distinction is important, for under a "suspension" maintenance men are permitted to keep the mines in readiness for the resumption of work at any moment, whereas a strike means a complete shutdown and a possible deterioration of the mine property. The willingness of the miners to make this concession was taken as an indication that the miner-operator conference called by the President had a fair chance for success.

Government Intervention

NO hint has been given as to which course Federal intervention will take if it actually becomes necessary. There appear, however, to be two alternative lines of action for the Administration. One possibility is the extension of protection to operators who wish to reopen their mines. It is regarded as extremely doubtful that President Harding would sanction this step, for it would amount to throwing the influence of the Government against the labor unionists. The Administration, of course, is extremely anxious to avoid taking sides.

The other alternative, which would not arouse the hostility of the miners, would be to establish Government control over enough mines to supply the absolutely essential needs of the country. The miners and operators could then be left to settle their dispute by themselves. The Government could distribute the coal produced in the mines it took over by an organization similar to that of the Fuel Administration of war days. Such a step would be extremely radical, and it is not believed President Harding would act until all other means had failed.

Such measures would merely be emergency steps, and would not solve the real problem, which can be settled only by the operators and the unions.

The strike is their controversy, in spite of the interest of the outsiders known as the public, and it can be settled only by an agreement between them. In order to be able to present to its readers a definite statement of the attitude of union

The Nation's Swiftly Diminishing Coal Pile

April 1
63,000,000 Tons

May 1
53,000,000 Tons

June 1
43,000,000 Tons

On April 1 the total coal reserves of the country were 63,000,000 tons. The normal rate of consumption is now

10,000,000 tons a month in excess of production from non-union mines. The minimum reserve for safety is 20,000,000 tons; a

A modern washery at work. In the old mining days any coal smaller than our present egg coal was considered useless and thrown out on the dirt bank as unsalable refuse. These dirty banks grew to enormous size before any thought was given to the possibility of utilizing the coal they contained. The coal dirt is now washed by hydraulic power down chutes to the washery where screens separate the coal according to difference sizes. (© International)

labor to the dispute, THE INDUSTRIAL DIGEST asked a selected number of union leaders to answer the following questions:

1. Do you think that the men were justified in resisting the wage reduction?
2. Do you think that miners should be paid on an hourly basis?
3. Are there too many mines in operation and should the less productive mines be closed?
4. What machinery do you think should be set up for the adjustment of wage disputes in the coal fields?
5. Do you think that government operation, ownership or supervision would be beneficial?
6. Do you think the strike will last long enough to create a real coal shortage?

Frank Farrington, president of District No. 12 of the United Mine Workers of America, in answering the questions as follows, showed that labor leaders are not in harmony as to the methods to be employed to win the strike.

"Answering question No. 1, I advise that I certainly do feel

that the miners are justified in resisting a wage reduction. Answering question No. 2, I advise that the miners are not now paid on an hourly basis, and I do not think they should be as I do not believe they would be able to secure an hourly rate that would enable them to earn as good wages as they can now earn working on a tonnage basis.

"Answering question No. 3, it is my opinion that the mining industry is at least 40% per cent overdeveloped. Answering question No. 4, I do not think any new machinery should be created for the adjustment of disputes. For more than a quarter of a century the mine workers and mine owners have been able to adjust their disputes by the means provided for in the various joint agreements, and I am satisfied that the present controversy could be adjusted in a satisfactory manner if Mr. Lewis would but abandon his stubborn position and allow us to make district agreements.

"Answering question No. 5, I advise that I am opposed to Governmental operation, ownership or supervision of mines so long as the administration of governmental affairs is in the hands of practical politicians who predicate their actions, not upon the merit of things, but instead base their judgment upon the effect their action will have on them politically.

And The Danger That Is

Impending

(Relative widths of piles used as basis of measure)

Danger

July 1
33,000,000 Tons

August 1
23,000,000 Tons

September 1
13,000,000 Tons

October 1
3,000,000 Tons

condition that might result the second week in August if meanwhile steps are not taken to end the coal deadlock. If, after

this turning point early in August, reserves continue to be depleted, industrial production will have to be curtailed.

During the last 30 years, the bituminous mines of the United States have lost, on the average, three working days out of ten. The chart above shows production, capacity, men employed, mine price per ton and days lost at the bituminous mines from 1890 to 1921—(Survey Graphic).

"Answering question No. 6, I advise that I cannot predict how long the strike will last, but my opinion is that if Mr. Lewis clings to his present position, which is that the operators from Indiana, Illinois, Ohio and Western Pennsylvania must meet him in an Interstate Wage Scale Conference, the strike will last until eternity."

Lee Hall, President of District No. 6, United Mine Workers of America, Columbus, Ohio, writes: In answer to the question (No. 1) Do you think the men were justified in resisting the wage reduction: "I answer the same by saying 'Yes,'—and do so for the following reasons: When the Bituminous Coal Commission made their report in 1920, which report was the basis for the settlement of the controversy then between the Mine Workers and Operators, they granted an increase in wages amounting to an average of (27%) twenty-seven per cent—while the Mine Workers had contended for a sixty per cent (60%) increase. In making this award of twenty-seven per cent, the Commission stated that in doing so, they expected there would be a reduction in the cost of living during the two-year period in which the contract was to be run, but to the contrary, we find an increase from the time the contract went into effect in 1920, until July, 1921. After that time there was some decline in the cost of living, though it was very small, and for that reason I contend the miners were justified in resisting a wage reduction.

"In answer to your question No. 2, I would answer 'No,' as the miners are not asking to be placed on an hourly basis; they prefer to work on the tonnage base.

"In answer to question No. 3—Are there too many mines in operation and should the less productive mines be closed? you ask two questions in this one sentence; first, there are too many mines in operation, as the coal industry is at least forty per cent overdeveloped. In answer to the last, should the

less productive mines be closed, I would not say that they should. To do so would probably work a hardship and injustice upon those who have their money invested in the mines that are now in operation. It would be just as fair to take the position to close down any other industry that may be overdeveloped, such as automobiles or any other kind of business, as it would be to close mines less productive.

"In answer to your question No. 4—'What machinery should be set up for the adjustment of wage disputes in coal fields?'—you do not explain what machinery you refer to; however, I would take for granted that you mean some Government machinery. I am opposed to any interference on the part of any Governmental agency in the adjustment of wage disputes in coal fields as they do not provide any machinery for the adjustments of disputes in any other industry, except railroads, and the Government machinery provided for the adjustment of disputes between the railroad workers and owners have failed in its purpose because the railroad companies have positively refused to comply with or be governed by the desires of the Railroad Labor Board, therefore I am opposed to any Governmental interference.

"In answer to your question No. 5—'Do I think that Governmental ownership would be beneficial?'—I am not as familiar with this question of Governmental ownership as I should be, and therefore decline to make any answer or comment on this section.

"Answer to your question No. 6—'Do you think the strike will last long enough to become a real coal shortage?'—I answer that question 'Yes,' and say that the time is here now, where there is a real coal shortage, and I predict that the coming winter will see the greatest coal shortage ever known in the history of this country, and with prices higher than even those that prevailed during and since the Great World war."

Consolidating Bucket Shop Losses

The gullible public has been fleeced of \$15,000,000, since the beginning of the anti-bucket-shop campaign; 30 Consolidated Exchange member firms have failed since then

THE failure of the stock brokerage firm of E. M. Fuller & Co., New York, as a result of which it is estimated that 16,000 customers will lose \$4,000,000, has aroused a flurry of resentment in the New York press against the Consolidated Stock Exchange, of which the Fuller firm was a member.

The Consolidated Stock Exchange is a secondary market, dealing in the stocks that are listed on the New York Stock Exchange. Prices on the Consolidated depend somewhat upon prices on the "big board," which is Wall Street's pet name for the New York Stock Exchange. When there was a fire in the big Exchange recently the Consolidated also closed down. Members of the Consolidated make things easier for the small speculator by trading in ten-share lots, whereas the official trading unit of the big Exchange is 100 shares.

Newspaper critics of the Exchange point out that 30 of the firms which failed since the campaign against bucket shops was started have been members of the Consolidated. They further assert that officials of the Exchange should have taken action against the Fuller firm before the disaster occurred.

"The story of the failure," says the *New York World*, "has no more amazing feature to most people than that the concern was permitted to remain as a member of the Consolidated Stock Exchange when, it seems, a cursory investigation by officials of the Exchange would have revealed the unsavory reputation of the firm's members, and also disclosed the fact that Fuller, aside from having a police record, had long been an associate of criminals."

"In the light of the recent record of the Consolidated Stock Exchange, however, the permission granted to the Fuller firm to continue in business as a member of that Exchange is not surprising."

"The Hughes committee, which investigated Wall Street, stated in its report that 'our investigation has indicated a lamentable indifference on the part of the management of the Consolidated Exchange to the prevalence of bogus transactions' and that the 'lack of the sense of responsibility calls for severest criticism.'"

"Considering the recent record of failures of Consolidated firms and the malodorous nature of these failures, the quoted criticisms of that Exchange, made years ago, would seem to apply today with even greater force."

"Since the campaign against bucket shops was initiated last spring more than 30 Consolidated houses have failed. Debts of these firms to customers approximate \$15,000,000. When final accounting is rendered by receivers they may be found to greatly exceed that sum. Recoverable assets of creditors are impossible to closely estimate. Taken collectively, these creditors may not obtain more than 10 cents on the dollar."

Even the New York Stock

Exchange has not entirely escaped the resentment aroused by the epidemic of brokerage house failures. An attempt was made during the latest session of the New York State Legislature to enact a law for the licensing of stock brokers which would have sorely irked the big Exchange. The passage of this bill was prevented, but the feeling which caused its presentation still remains. The District Attorney of New York County has openly avowed that he will fight for the governmental control of all brokerage activity.

Leaders of the Stock Exchange decided that the way to arm themselves against these attacks was to clean house thoroughly. The leader in the house-cleaning movement is Seymour L. Cromwell, president of the New York Stock Exchange, who periodically issues terrifying pronouncements to member houses that the Committee on Business Conduct will get them if they don't watch out. Mr. Cromwell argues publicly that the Stock Exchange itself is the best possible licensing agency for the protection of the public, and apparently he intends to make his words good.

The New York Stock Exchange is now circulating a questionnaire among its members inquiring, in a large list of items, about their business condition. Mr. Cromwell expects that the data which will be presented in response to this questionnaire will disclose any sore spots that call for action by the board of governors.

Stock Exchange Head Explains

SAMUEL UNTERMYER, in the course of his inquiry into the merger of the Midvale, Republic and Inland steel companies, condemned the practice of dealing in securities "when, as and if issued," a practice which is indulged upon the New York Stock Exchange as well as on the smaller exchanges. Mr. Cromwell, replying to this criticism and explaining the useful functions of the Stock Exchange, said:

"The Exchange is now a market for upward of 700 separate stocks and over 1100 different issues of bonds, the total value at par of these securities amounting to some \$40,000,000,000. A market of this character performs a great public service in that it keeps a vast proportion of the national wealth in liquid form. How efficiently the Stock Exchange performs the functions above referred to may be gathered from the fact that almost any day securities of upward of \$100,000,000 par value are bought and sold on the New York Stock Exchange, and seldom are there any disputes over transactions."

"We have heard a great deal concerning the question as to whether or not securities may be properly dealt in on the floor of a securities exchange before the same securities are actually issued in definitive

Just when business is beginning to sit up

The Foire de Paris, France's Great Annual Sales Fair

This picture shows but a corner of the exposition grounds on the Champ de Mars, Paris, giving an idea of the type of buildings used to house the wide range of exhibits. There were 4500 exhibitors this year, all French manufacturers, and some 2,000,000 visitors, a large number from foreign countries.

The Village Store Idea in Industry

How Europe's method of annual fairs differs from the American plan of specialized expositions

INDUSTRY in Europe habitually makes use of a sales method that is virtually unknown in the United States—the industrial fair. Once or twice each year the manufacturers of an entire region bring their wares to a commercial center such as Leipzig or Lyons or Dresden, where buyers congregate. All kinds of goods are exhibited, from phonographs to fabricated houses, and the volume of sales is great.

In this country we have expositions, but they do not resemble these European events. Our great fairs, at which all kinds of goods are shown, are held only on rare occasions, commemorative of important historical occurrences. They are spectacles, not ordinary periodical merchandising devices. The coming Philadelphia sesquicentennial exposition will be no more comparable to the Leipzig spring fair than John Wanamaker's Philadelphia establishment is comparable to the general store at Horicon, N. Y.

In particular industries we have adopted the idea of periodical expositions. We have our annual automobile show, our chemical exposition, our silk exposition. These differ from the European fairs not only in the fact that they concentrate on one product alone, but also in that they are shows rather than sales events. People attend them to look rather than to buy, and sales are made through other channels.

Known officially as the "14th Foire de Paris," the annual

exposition of French industrial products just held at Paris has been a greater success this year than ever before, either in pre-war years or since the armistice. The number of French manufacturers exhibiting showed a large increase over last year, and the crowds thronging the grounds every day of the fair broke all previous attendance records and kept the gendarmes busy handling traffic.

The fair opened May 10 and ran until May 25, and while the committee has not yet given out any figures to indicate the volume of business done by exhibitors, it is safe to say that the amount of buying done, when made known, will reveal a healthy business state of mind and pocket-book.

The Foire de Paris has grown from year to year until now it is in fact a national exposition, and although French-made goods only are permitted to be shown, the number of industrial and business men from foreign countries who came this year and bought machinery and equipment, made in France, should cause foreign trade experts to look up and take notice.

There were 4500 exhibitors this year, compared to the 3800 in 1921, and it is estimated that the attendance totaled more than 2,000,000 people.

Agricultural implements, electrical machinery and electrical appliances, gas engines for industrial and farm use, modern office equipment and models of small dwelling-houses of the

type being erected in the devastated regions were among the exhibits attracting the greatest amount of interest.

Features of France's Annual Fair

THE majority of agricultural implements shown were of the horse-drawn type, although a few motor-driven machines were present. France is not a country of big farms, and the horse has not yet been displaced in the rural sections. Gas engines are widely used on the farm generally, for pumping, threshing, etc., and the exhibits of farm lighting sets (including several driven by windmills) attracted much attention. Mention must also be made of the comprehensive line of moderate-priced farm bathroom equipment, made possible, more or less, since the development of the small motor-driven farm pump. These sets are sold with either gas or oil water heaters, galvanized tub and necessary piping, the prices, installed, ranging upward from about \$75 American money.

France is wide-awake to the saving to be effected by the use of labor-saving and time-saving machinery if and when it means a saving in high-priced labor, but where common labor, only, is involved industrial plants and farmers both sometimes show a tendency to stick to old-time methods if the change to the new means too great an initial expenditure.

A rather striking illustration of this characteristic feature of the way Frenchmen work, both on the farm and in industrial plants, was afforded by the exhibition of two-wheeled horse-drawn carts (wheels nearly six feet in diameter) alongside the really splendid showing of the most modern types of self-loading and dumping industrial motor trucks. These lumbering carts, capable of carrying tremendous loads, are still extensively used in France. For hauling heavy machinery and freight on farms and in cities where time is not an important factor in transportation, they are more economical than motor-driven vehicles. At least that is what one Frenchman said when asked to explain their presence at an exhibition of modern machinery and methods. When one remembers that motor fuel in France is almost three times as expensive as in the United States, there seems to be something to the argument.

The display of electrical machinery, comprehensive in other respects, fell below expectations as regards exhibits of radio telephone sets. Only a few firms had such apparatus on dis-

ago on radio telephony. The interest here is hardly more than an echo of the tremendous fad in the States. Six months from now, however, it may be a different story.

The exhibits of essential machinery and moderate-priced dwelling-houses were of more than passing interest. More than a dozen firms in France manufacture houses and are selling them in great numbers in northern France. One firm, which specializes in a four-room concrete farm dwelling, have built 275 such houses in the Department du Nord and 25 in Meurthe et Moselle. Prices for such houses range from 3000 francs for a two-room wooden house up to 18,000 and 20,000 francs for concrete houses of four and five rooms. Easy terms of payment are arranged for the buyers.

Modern office furniture and equipment, prominently dis-

The industrial haulage section of the Foire de Paris, showing types of motor-driven vehicles on display.

played, gave evidence of the awakened interest of French business men in making their offices efficient and comfortable. Desks and filing cabinets of the more expensive grades were shown in considerable number. In this same building it was interesting to note that more than a score of French advertising bureaus had stands, and gave out information and literature explaining the features of the services they offer French business houses.

Advertising in France

WHILE advertising is generally taking root more firmly year after year in the French commercial structure, it is still regarded by the general run of people as a sort of luxury, to be indulged in by a firm only after it has reached a certain stage of importance or success. Novelty window displays, striking lighting effects, and small automatic electric flash signs, however, seem to be looked upon as more legitimate means of publicity than the printed word in newspapers and periodicals. Accordingly advertising concerns offering for sale these various appliances for "mechanical" advertising had crowds around their stands, whereas the concerns offering the prospect a service of art work and printed words found time hanging heavily on their hands.

One "attention-getter" of very pronounced effectiveness was the electric siren mounted on top of the booth of a manufacturer of compressed air and electric alarm devices. This siren was the same type as was used throughout Paris during the war to warn the Parisians of approaching air raids, and its weird cry sounding through the fair grounds brought the progressive manufacturer's agent more spectators than he could accommodate.

The methods employed at the Foire de Paris have been in vogue in Europe for many years, particularly before the war. As the countries recover from the effects of the war, the fairs are becoming more numerous as a means of meeting the trade competition from foreign countries. This year's French fair proved its value particularly as a means of keeping trade at home.

One of the principal aisles of the agricultural machinery exhibition section of the 14th Foire de Paris.

play—certainly not over half a dozen—and there seemed to be no actual demonstrations being made. The concerts now being broadcasted from Eiffel tower wireless station would have stimulated interest, but apparently none of the firms exhibiting radio telephone sets were giving actual demonstrations. France is where the United States was about a year

When Economic Doctors Disagree

Expert diagnosis of industrial ills often results in confusion to the business man, but certain fundamentals may always be counted upon to run true to form

PROPHETS are much in demand nowadays. The course of business has been disturbed, and people are anxious for guidance on the probable trend of prices and business conditions in general. In response to this demand great numbers of diagnosticians of economic conditions have arisen, and many persons, more or less trained in economics, are offering forecasts of how things will turn out.

Is there anything in these prophecies? Can the business man learn anything valuable by reading the outpourings of these prophets, or by following for himself the various statistical "indices" of business?

Certainly no one should place too much reliance on detailed, specific prophecies of economic events. The prophets disagree among themselves too much, and they have often been found wrong. Yet there is an increasing tendency among business men, bankers and really competent economists to assume that something actually can be learned, by the cautious study of statistics, about the general tendency of business movements.

Economic science is, however, in so unscientific a state that everyone must determine for himself whether or not the statistics with which he is dealing are reasonably reliable. The interpretation of those statistics is also a matter in which personal judgment must be used.

Charts showing the variations over a period of years in certain series of statistics are a favorite device of the economic prophets. The graphs in the accompanying illustration, which were prepared by Leonard F. Ayres, vice-president of the Cleveland Trust Co., are excellent examples of this sort of thing. They present records of the fluctuation in pig-iron production, stock prices, bond prices and interest rates during six great business depressions that have taken place in this country since the Civil War.

In each case, the charts show that the recovery has been marked by increasing industrial production, rising prices for stocks and bonds and low interest rates. The black silhouette background shows the course of pig-iron production for the

four-year periods. The line at 100 represents the average monthly output during the periods, and the black silhouette shows for each month the degree to which the output was greater than the average, or below it.

The three lines running across the diagram represent the average market price each month of ten high-grade railroad bonds, the average price of ten high-grade railroad common stocks, and the average quotations for choice 60 to 90 commercial paper in New York. This last line, showing the course of interest rates, has been drawn after multiplying the quoted rates by ten, so that 60 on the diagram means 6%.

Three significant features may be noted. The first is that in past depressions the high point for bonds was reached about 14 months after the low point for pig-iron production. The second is that the high for stocks came approximately two years after the low point of pig-iron production, and the third is that low interest rates continued for about one year and a half after the lowest point for pig iron.

Pig-iron production has been used in these diagrams to represent the course of industrial activity. Its figures are almost the only statistical series of industry running back by months in adequately reliable records over the past 40 years. Moreover, these data constitute a sensitive and trustworthy barometer of industrial activity, for almost every sort of manufacturing operation is dependent on iron for material, machinery or construction. It may be accepted as a generally valid proposition, according to Mr. Ayres, that when pig-iron production falls off, general manufacturing activity is declining, and when it increases it is because it is expanding.

The Object of Charting

THE object of compiling and charting such information is, of course, to enable one to judge the future from the past. Such judgment is difficult because the past does not repeat itself accurately. Conditions are different in every epoch, and it is difficult to allow for the variations.

This point is made by the Harvard Economic Service.

Diagram 1—The long and slow depression from 1883 to 1886.

Diagram 2—The severe and irregular depression beginning in 1893, with crop failures in that and the following year, and

partial recovery in 1895, followed by further depression in 1896. **Diagram 3—**The short depression of 1903 and 1904, sometimes called the rich man's panic. **Diagram 4—**The depression of

another economic prophet, which thinks that this time the past will not be fully repeated. This organization points out that after each of the two important periods of inflation which took place in the 19th century, prices dropped at least as low as the levels preceding the inflation, but it does not believe that the same thing will happen now.

"The high prices prevailing during the first half of the second decade of the 19th century, which were due to inflation caused by war, were followed by a long period of declining prices which continued, with temporary interruptions, until 1849, when the gold discoveries in Australia and California enormously increased the production of the yellow metal and inaugurated a period of rising prices," says the Harvard Economic Service.

"In the United States this upward swing was succeeded by currency inflation during the Civil War; and this, in turn, was followed by a period of drastic deflation which, by 1878, had brought prices back to a level lower than that prevailing in 1861. During the '60's gold prices in England pursued the even tenor of their way, but in the early '70's they entered upon a long decline which lasted until 1897. In the United States, which had returned to a specie basis in 1879, a similar movement was recorded; and like developments occurred in all other countries which had a gold standard. The upward swing of commodity prices from 1897 to 1914 was due to another phenomenal increase of gold production, resulting from the opening of the South African mines and the introduction of new and improved methods in quartz and placer mining.

"The inflated prices of the last eight years require no comment except that the great increase in the United States was due to the expansion of bank credit, not to inconvertible paper money, and to prodigious imports of the yellow metal which enabled credit to expand without causing a departure from the gold basis. From this historical record the natural and plausible inference has been drawn that just as prices after the two previous periods of currency inflation reverted to their former levels, so in the present instance they must return to something like the level that obtained in 1913.

"But historical parallels are likely to mislead unless care is taken to determine whether all important conditions are the same. From 1815 to 1848, and from the late '60's to 1896 they seem to have been so; but some of the leading factors in the present situation are very different from those operative in the previous instances, so that judgment should be suspended until these points are carefully examined."

The Service then goes on to compare the present with previous situations. After former wartime periods of inflation, it says, the United States was able to extinguish its national debt quickly and without great hardship by means of customs duties, excise taxes and public land sales. Therefore a drastic return to pre-war prices was possible. If the national debt

had remained unreduced, falling commodity prices would have magnified the debt and thus proved a great hardship. At present, the Service says, the national debts of the world cannot be extinguished quickly, and a drastic drop in commodity prices would be so irksome as to cause political disturbances.

Moreover, it is pointed out, the present differs from the past in that a world-wide return to the pre-war gold parity of currencies seems impossible today. Complete deflation of the currency of the world cannot be effected. Present high prices, of course, are due largely to continued world inflation; and if world currencies cannot be deflated, prices cannot drop.

The most interesting difference between the past and the present which the Service has discovered has to do with the gold supply. According to the quantity theory of prices, commodity prices vary directly with the size of the gold supply. The annual increment to the world's stock of the yellow metal, it is pointed out, has decreased considerably since the war, but is still considerably larger than the annual increment which the world received during previous periods comparable to the present.

"The evidence shows that the annual increment to the world's monetary supply has fallen from a pre-war level of \$232,000,000 to \$150,000,000," says the Service. "This is a substantial decrease, but it does not justify alarm concerning the future course of gold prices. Before the war commodity prices were increasing at a very substantial rate, with an annual gold increment of \$232,000,000; and there was general complaint of the increasing cost of living, which had led to the appointment of numerous parliamentary and legislative commissions to investigate the problem. In view of this fact it would seem that an annual increment of \$150,000,000 should be ample to prevent a decline of prices during the present decade."

This is quite a different conclusion from that of Mr. Ayres, who says: "It is probable that we are entering upon an extended period of falling prices, broken by occasional shorter periods of rising prices."

Thus the experts disagree. Should one conclude, therefore, that the judgment of the experts is worthless, and that attempts to diagnose business conditions are useless? A preferable conclusion is a less drastic one: that economic diagnosticians, like their brothers in medicine, are wise but fallible, and that one should take advantage of their wisdom conservatively, and use one's own judgment in accepting or rejecting their pronouncements.

1907 and 1908, accompanied by acute industrial disturbances, and by financial difficulties so serious as to provide the final illustrations and arguments necessary to bring the Federal

Reserve system into existence. *Diagram 5—Depression preceding great war, with its quick recovery to war-time prosperity. Diagram 6—The depression following the war with Germany.*

Your \$100,000,000 Investment

You are a part owner of one of the finest power plant projects in the world, lying idle at Muscle Shoals because your Uncle Samuel has not decided how to dispose of it

ACROSS the Tennessee River near Florence, Ala., stretches a strip of concrete and scaffolding—an unfinished dam. About it is gathered everything that goes to make up a great manufacturing center; two large nitrate factories, a steam-electric power plant, quarries, water works, lighting plants, homes for employes, schools, and assembly halls. All are idle and in various conditions of completion and repair. In addition, also idle, is a complete set of equipment for dam building; a three-mile railway line to haul materials, 45 locomotives laid away in grease paint on a siding, a fleet of barges and dredges to bring sand and gravel from the lower river channel, and the largest concrete mixer in the world.

The section of the Tennessee River in and beside which this idle equipment lies is known as Muscle Shoals, and this name has been given to the entire unfinished project. The Congress and press of the United States are now engaged in discussing what is to be done with it.

The cost of the project to taxpayers to date has been estimated by various authorities at sums ranging from \$106,000,000 to \$167,000,000. Congress has expressed an ardent desire to prevent this money from going to waste, but has been unable to agree on the method of continuing the work so that results can be shown for the expenditure. Henry Ford has offered to take the plant over and run it, and Congress is now debating his offer.

Muscle Shoals is one of the largest industrial projects ever attempted. Its hydro-electric plants are expected to develop 1,000,000 horsepower. The people of the South believe that the completion of this great power unit would give a new impulse to their industrial life, and would make the Tennessee valley a new national industrial center. Muscle Shoals, they say, is situated in the midst of raw-material supplies—including calcium limestone deposits, coal and coke works—that would make possible factory development in the neighborhood to an extent previously unheard of. Farmers throughout the nation have been led to expect that the development of Muscle Shoals will mean an abundance of cheap fertilizer for them. The extent and seriousness of the agitation over Muscle Shoals is to be explained by the fact that these visions hinge upon the development, as well as to a desire to prevent the waste of more than \$100,000,000.

* * *

Ever since the United States has been a nation this section of the Tennessee River has been considered an unusually favorable site for a dam system. The river drops 133 feet

in seven miles at Muscle Shoals, over a shifting bed, and the possibility of a successful dam, with locks, both to make the river navigable and to develop water power, has always been apparent. Since the beginning of the 19th century plans for the development of the Shoals have been considered by the Federal Government, which repeatedly investigated and then dropped them for one reason or another. Work was started on a dam in 1820. In the next 70 years several attempts were made to put a development through, and in 1890 a canal, paid for jointly by the United States and the State of Alabama, was opened to navigation. This canal is 16 miles long and contains 11 locks—and is not much used. In 1910 a commission of engineers recommended to Congress that a dam be built at Muscle Shoals for power and as an aid to navigation. Four years later drill tests were made and the dam pronounced feasible.

The Start of the Muscle Shoals Project

WHEN the United States entered the war one of the nation's first needs was a great quantity of nitrates for explosives. Speed was essential; cost did not matter. It was decided that the quickest way to get the nitrates was by the construction of a plant for the fixation of the nitrogen of the air, a process which requires great power facilities. Muscle Shoals presented itself as the ideal place for such a plant, and accordingly the war Government started the project which the present Government finds itself called upon to finish.

The plans called for the construction of two dams to harness the Tennessee, and two plants to make nitrates, one by the synthetic ammonia process similar to that used in Germany and the other by the cyanamid process used at Niagara Falls. Work on the dams proceeded slowly, but the nitrate plants were constructed with comparative speed. A steam-electric plant was built, supplying power to nitrate plant No. 2, which made several thousand tons of ammonium nitrate before the armistice was declared.

On armistice day the larger of the two projected dams, known as the Wilson Dam, was about 5% completed. Work was continued until May 1, 1921, when the funds on hand were exhausted. At this time the dam was about 35% finished, and materials representing a larger percentage of the expected total cost of the dam had been gathered on the site. The project rests in this condition today.

The Wilson Dam, when completed, will be 160 feet wide at the base, with a 59-foot apron

(Worcester Daily Telegram)

The "honk" heard throughout the country, but not by the gentleman in front.

to prevent abrasion. The driveway on top will be 133 feet from the river-bed, and the entire dam will be 4600 feet long. A 95-foot power head will be used to operate generators with a capacity of 600,000 horsepower, more than that generated by all the hydro-electric plants now operated in Alabama, Georgia, South Carolina, North Carolina and Tennessee. The other dam, 17 miles farther up the river, will be 50 feet high, and will develop 250,000 horsepower on a 42-foot power head. Two locks will be needed to permit vessels to pass the Wilson Dam, and one will be needed at the other barrier.

Those who dream of making the Tennessee valley the great industrial center of the nation say that eventually a dam should be erected for every five-foot drop in the river. Oil-burning, self-propelled barges should be operated past these dams through a series of canals, to carry supplies for the farms and factories that will spring up side by side along the river.

What a Power Company Would Do

OF the offers for the purchase and operation of property at Muscle Shoals received by the Government, those of the Alabama Power Co. and of Henry Ford are the most important. The power company offers:

- (1) To complete the Wilson Dam at its own expense, under a license to be granted to it under the Federal Water Power Act.
- (2) To furnish free to the Government, or anyone it may designate, the second 100,000 horsepower developed by the Wilson Dam, for use in producing fertilizers and munitions. If the use of this power is discontinued by the Government, the Alabama Power Co. offers to purchase and pay for it according to a schedule to be set forth in the license.
- (3) To buy the Government's interests in the steam plants at Muscle Shoals for \$5,000,000, less an amount agreed on to cover the cost of locks and navigation structures at the Wilson Dam.

(4) To operate and maintain the power plant, dam and gates, and to supply free of charge the power required by the Government to operate the locks.

(5) The project covered by the license is to expire in 50 years, and the Government is to have the right, in time of emergency, to take over the plant to manufacture war materials.

Henry Ford's Proposal

HENRY FORD offers to take over Muscle Shoals on terms which may be summarized as follows:

- (1) He is to buy the two nitrate plants, the Waco quarry and the steam plant for \$5,000,000.
- (2) The Government is to pay for the completion and maintenance of both dams, and build locks in connection with them.
- (3) He is to get a 100-year lease on the dams and power plants, renewable in perpetuity.
- (4) He is to pay \$1,680,000 a year for 96 years as interest on the Government's investment in the dams and power plants, and \$46,547 a year for 95 years to be invested at not less than 4% as a sinking fund.

Congress is now deciding, amid much tumult and shouting, whether it will accept these terms. No other offer worth considering has been received.

Mr. Ford says that Muscle Shoals presents an unprecedented opportunity for service to humanity. He would use the Shoals as the focal point for all his humanitarian ideas. He would have the Government pay for the dams by issuing paper currency against units of energy to be produced by the power plants, and thus demonstrate the needlessness of a gold standard, confound the international bankers, and pave the way for the end of wars, which (he says) the bankers cause to be waged for their own benefit. He would develop on the banks of the Tennessee factories using the labor of

Money Rates Bear Watching

CANNY investors these days are watching money rates closely. A sustained rise in interest rates, the experts tell us, is one of the surest signs of the end of a rising security market. Since prices on the New York Stock Exchange have shown a decided wavering tendency lately, it has become increasingly necessary to watch fundamental factors such as money rates to know just where one stands.

Two outstanding events in the money market in June were the reductions in discount rates by the Bank of England and by the New York Federal Reserve Bank. Both these events gave courage to bulk speculators for the long pull, who interpreted them as indicating that, whatever the stock market might do today or tomorrow, security prices, in the long run, are still on the upswing.

The central banks, in thus reducing their rates, gave recognition to a condition that had long since shown itself. Long before the New York Federal Reserve Bank reduced its rate to 4%—the figure, by the way, from which it was raised when credit first tightened in 1919—the actual drop in interest rates in the open money market had been registered by the rise of the 4½% Liberty bonds above par and the setting of a 3½% rate by the United States Treasury on a new short-term loan.

Those who hailed with satisfaction the continued drop in money rates throughout June were not discouraged by the fact that call money rose sharply at the very end of the month. This tightening, they said, was merely temporary, due to the approach of the July 1 settlements. It indicated the withdrawal of money from New York to banks in the interior, a reversal of the recent movement that brought interior funds to New York to aid the Government in making its June 15 payments. Some bankers said that the tightness would continue until the July 1 payments had been taken care of, whereas others expressed the opinion that the increase in interest rates would bring out idle funds that would quickly force the rates down again. No one seemed to think that the tightening was more than temporary. The opinion remains that money rates will soon resume their downward movement.

The Mexican Petroleum Flurry

MEXICAN Petroleum excited the stock market in the closing half of the month. This, and a few other highly speculative shares, led the trading over a period that would otherwise have been dull. The sensational rise in Mexican Petroleum, which increased 40% in market value in only eight days, induced the Committee on Business Conduct of the Exchange to conduct an investigation into dealings in the stock. The committee found nothing to call for official discipline. Nevertheless, the actions of the stock made it quite clear that a group of speculators had achieved something resembling a corner, and administered some nasty blows to a venturesome short interest. The rise in Mexican Petroleum was accompanied by the announcement of a highly favorable annual report

of the company's business; but the report, though it showed an increase of nearly \$7,000,000 in annual profits, was not sufficiently unexpected to justify so violent a jump in the price of the stock.

"Whatever the exact facts of the matter, open manipulation of a corner has not characterized this episode," says the New York Times of the Mexican Petroleum flurry. "Such an undertaking would be doubly dangerous because of the attitude of the Stock Exchange authorities and because of its effect on the rest of the market."

"The immediate effect of this abnormal and artificial movement was what always happens first on occasions of the sort—a half-panicky rush of short sellers in other stocks to buy back their shares. The next was to cause doubt and hesitation in the market. The exceedingly bad effect of such episodes on confidence in the machinery of the stock market are well enough known to explain that second attitude."

Bond Market Still Firm

THE bond market in general has remained firm throughout the ups and downs of the stock market. There is some difference of opinion as to what may be expected in the future. Some experts are inclined to doubt that the highest grade issues will go much higher. Brighter prospects are held out for the middle grade and cheaper bonds, which involve a certain amount of risk. As general business conditions improve, it is said, the ability of the corporations issuing these bonds to fulfill their obligations will be clearer, and therefore the prices of the securities will rise. A substantial rise in gilt-edge bonds, however, could not take place without a further substantial drop in money rates, regardless of any improvement in general business conditions.

The Two Million-Share Day

THE great difference in the significance of a 2,000,000-share day on the New York Stock Exchange two and a half years ago and today is strikingly illustrated in the chart herewith. On October 23, 1919, for example, prices then being close to the peak of post-armistice inflation, 308 different issues were traded in on the Exchange; the total sales for the day amounted to 2,325,000 shares; and the market value of these shares was \$214,000,000. On last April 17, on the other hand, although 143 more stocks were traded in than on the earlier date, and although total sales ran close to 2,000,000 shares, the market value of these shares was only \$94,000,000. In other words, although, as a result of many additions to the

list, 46% more stocks were active on the later day, the market value of the turnover was but 44% of that on the earlier date. Put in another way, a 2,000,000-share day during last April provided a turnover equivalent to what would have been furnished by 1,070,000 shares on October 23, 1919. Accordingly, as a result of the lower prices now prevailing, a 2,000,000-share day now represents an amount of business roughly equivalent to a 1,000,000-share day before the great break in post-war prices.

The Difference Between a 2,000,000 Share Day in 1919 and in 1922.—(New York Evening Post.)

IN THE MANAGER'S OFFICE

Control of Factory Overhead

OF the three factors in the cost of a product—material, labor and factory overhead—the management can exercise the greatest control over factory overhead. The other two items are determined largely by external conditions. A method of reducing factory overhead by keeping the department head informed of the expenses of his department is outlined by E. F. Lindewirth in *100% Management*.

A list of standing account numbers, or "Card of Accounts," is issued, so that every department will be able to charge each item on a stores requisition or time ticket to its proper account number. As requisitions and time tickets come to the cost department extensions are made and the amounts posted to the cost sheet. One sheet is opened for each department and shows material and labor both in itemized and summarized form. After all entries have been made for the month, totals from the cost sheet are posted to a departmental expense form. This record shows the figures for three years and provides the basis of a budget. Department heads are supplied each month with an itemized record of the expenses of their departments. This presentation of the facts forms the incentive for a campaign of cost reduction within the department.

Cost Department Cooperation

LINKING the work of the cost department with that of general accounting is described by A. T. Rickards in *System*: (1) All supplies are kept in storerooms and may be drawn only on requisitions, copies of which go to the cost department; (2) all workers use time tickets on which time is charged against a job or lot number and the tickets sent to the cost department; (3) all miscellaneous or overhead expenses are distributed departmentally.

These three elements are bound up in determining cost, and each is controlled by an account in the general ledger. Monthly inventories are taken and monthly statements covering all operating expenses are made and balanced with the general ledger account. A separate statement for each department is sent monthly to each department head.

Before this plan was introduced each department supervisor was held responsible for the cost of his department. This supervision, although as close as possible, seldom gave figures which would enable the supervisor to know his monthly position. The accountability of the department head is now actual, a standard cost is established and overhead reduced.

How to Make a Budget

A PLANT manager, relating his experience with budgets in *Factory*, regards an accurate cost system as the whole basis of budgeting. To establish a budget plan it is desirable to have at least three or four years of accurate and detailed cost figures. In addition, an executive is required who has been in close contact with the compilation of such figures.

Costs must be published throughout the plant and the interest of executives, department heads and foremen aroused or the quotas set up will appear unreasonable to some and full cooperation will be lacking. The exact method of cost-keeping is not so important, but it is important that past costs be carefully itemized to obtain shop overhead, or the percentage of expense charged to productive labor. With

these data the relation of costs and volume of business may be adjusted to insure almost any reasonable profit desired.

To set up a budget that applies when volume changes, tables are prepared showing the amounts allotted to each major item for each increase or decrease of business based on the range of business expected during the year. These increases or decreases may be assigned values in proportion to the size of the plant. Assuming that the minimum business is likely to be \$120,000 monthly and the maximum \$240,000, the tables are made to show allowable expenditures in each department for an incoming monthly business of \$120,000, of \$130,000, \$140,000 and so on up to \$240,000.

With these budget sheets prepared in detail for each department, the announcement at the beginning of the month that a certain quota of business is expected constitutes a notification to department heads of what their allotted expenses may be. These predetermined figures are a convenience for the executive and save valuable time. Each month a complete report of actual performance is issued and compared with the budget figures set.

The Why of Scientific Planning

ONE of the most profitable results of scientific planning is the ironing-out of the seasonal curve in industries whose production is governed by the period of the year. Howard H. Wiley, in *100% Management*, describes a control of the seasonal factor which has warranted an increase in production during the dull season from 20% to 90% normal capacity. The production department lays out its plan for a six months' period. Each job is analyzed by the planning department and a detailed schedule worked out. The date of delivery being known, by working back through the schedule the time each class of material is needed can be determined. When these details have been worked out, the schedule is posted on the planning board, where it becomes a graphic record of essential information. The head of each department knows in advance what he will have to handle and when. The schedule shows at a glance all open time and thus becomes a basis for the work of the sales department.

As all planning is done before the work reaches the plant, productive work begins immediately and by a simple follow-up is kept up to schedule. This follow-up, or daily report of work in process, is made by the shop clerk or timekeeper, and shows the machines operating, the job and the number of pieces processed. From this record the production manager can detect any departure from schedule, investigate the cause and remedy the difficulty before it becomes serious.

Scientific planning promotes greater efficiency in every department, increases the effectiveness of the sales department, coordinates the work of all departments and enables the plant to deliver in contract time.

Testing the Clerk's Intelligence

THE use of intelligence tests has been confined more or less to the selection of junior executives, skilled factory workers, or salesmen. H. G. Kenagy in *Forbes* believes that the application of such tests to office workers—clerks, typists, stenographers and secretaries—would increase the efficiency of the average business office by as much as 50%. The degree to which intelligence is a factor in clerical efficiency is much

greater than most employers suppose. In the situation illustrated by the chart on this page, an intelligence test differentiated between good and poor stenographers with more than 84% accuracy.

Companies which have established training schools for the development of workers have experienced the fact that many unfitted, but enthusiastic, employees take up courses which they later drop. An intelligence test would eliminate those who are not mentally able to pursue the subject chosen. Charts I and II indicate that a test score of 60 is a good dividing line between success and failure in selecting applicants for a training school. Each dot or circle in these two charts represents one individual in the school.

The same test applied to stenographers actually employed in a business office confirmed the statement that a certain level of general intelligence is essential to satisfactory stenographic work. Results are indicated in Chart III. A second group to which the test was applied consisted of both stenographers and private secretaries. Chart IV shows the average higher intelligence required for secretarial work. In Chart V is pictured the scores made by fourteen stenographers rated by their employers as exceptionally good.

General intelligence is not the only factor to be considered in selecting office workers but it is one of the most important and has not been given the consideration it deserves. The use of intelligence tests will reduce turnover with a consequent reduction in general overhead.

Importance of Properly Designed Chairs

FATIGUE receives comparatively little consideration by manufacturers, notwithstanding the attention paid it by industrial engineers. The average manufacturer does not seem to realize fully the close relationship of fatigue and production, or to recognize it as an item in manufacturing costs that can be reduced considerably. Irving Salomon, in *Industrial Management*, declares that correctly designed seating decreases unnecessary fatigue more than any other single factor. Of all the causes of fatigue, seating is probably of the greatest importance because it is the most direct.

The practice of purchasing shop or office seating on the basis of what is cheaper to buy, and not what is more satisfactory to the occupant, should be discontinued. A careful analysis of seating requirements should be made in every plant, large or small, not as welfare work, but for the personal benefit gained in greater production.

A chair or seat, to be correct scientifically, must be gauged

Relation of Intelligence to Stenographic Ability.—(Forbes Magazine.)

according to individual differences in stature, either by adjustable features on the equipment itself or by assorted heights and styles carried in stock. Such seating recognizes each worker as an individual, while a standard non-adjustable chair supplied for all workers on a given operation fails to do so and frequently abuses human organisms.

Height, seat, back-rest and foot-rest are given as the four elements in the construction of seating. The general specifications of these are dependent upon the factors involved in each operation. These factors are: (1) Height of working surface of machine or bench, including obstructions or mechanical interferences below the working surface and interferences in arm movements; (2) Nature of the operation, involving location of supplies, disposition of finished work, leg movements on pedals, whether the operation is repetitive, continuous or varied, and

the natural fatigue occasioned by strenuous or monotonous work.

The procedure, in making a study of seating, consists of four steps: (1) Analysis or time study of the operation, dividing it into its various components; (2) Study of the bench, machine or working surface; (3) Design of the stool or chair; (4) Thorough test of a few chairs made according to the specifications.

Dollars from Scrap

WRITING in *100% Management*, E. Karl Wennerlund points out savings possible by the intelligent disposal of scrap. A study of the scrap business disclosed that proper sorting and classifying would result in at least a 25% saving on scrap loss.

A supervisor was placed in charge to advise on the classification of materials and seek the most profitable markets. The actual sales transactions were left in the hands of the purchasing department. As a protection, dealers in scrap were classified and an "approved list" prepared. When a sufficient quantity of scrap or by-products accumulated, dealers on the list were notified to bid and the material disposed of at the maximum price.

Retail Clothing Down 42 Per Cent

Retail clothing prices have dropped 42% since July, 1920, and a further decline is expected, according to the National Industrial Conference Board, which has made a survey of the clothing industry. Between November, 1921, and March, 1922, the average cost of clothing decreased 5%.

LABOR

The Railroad Strike

NEARLY 400,000 railroad employees were called out at 10 a.m. July 1 by strike orders signed by the six craft presidents of the railroad shopmen's organizations. The text of the strike order follows:

"In compliance with the strike vote, all shop craft employees below the rank of general foremen are hereby granted sanction to suspend work 10 a.m., July 1, on the railroad and Pullman shops in the United States. Notify all outside points. Wire number responding and number remaining at work.

"William H. Johnson, International Association of Machinists.

"J. W. Kline, International Brotherhood of Blacksmiths, Drop Forgers and Helpers of America.

"J. A. Franklin, International Shipbuilders and Helpers of America.

"J. J. Hynes, Amalgamated Sheet Metal Workers' International Alliance.

"James F. Noonan, International Brotherhood of Electrical Workers.

"Martin F. Ryan, Brotherhood of Railway Carmen of America."

The Railroad Labor Board has already taken steps to block the strike by calling railroad executives and union officials before it for a conference. Thus the long-heralded rail strike gets under way. In view of the fact that there is very little possibility of the Labor Board's rescinding its decision, and considering the probability that the Government will step into the breach with injunctions or equally stringent methods to stop the strike, the chance of success for the unions seems slight. Then, too, it is very probable that actions brought by the railroads under the Coronado decision will have a salutary influence in holding back the strikers.

The Harding Administration has already stated that it will take action in case of a railroad strike and will back up the Labor Board's decisions to the limit. Business feeling throughout the country is strongly in favor of the Administration's position and there seems to be no doubt that any action the Government might take would receive the hearty approval of industrial executives. The general public is tired of strikes and little sympathy can be expected from this source. The present likelihood is that the strike will dwindle down to the removal of a few key men from strategic positions, thereby striking the greatest possible blow at the railroads with a minimum withdrawal of men.

In any event, it is certain that traffic will be held up to some extent and this will not improve the situation which will arise next fall when the car shortage will be severe.

Of course the important factor in the coming car shortage is the renewed shipments of coal when and if the strike is ended this fall. Industrial fuel stocks are being depleted at the rate of about 10,000,000 tons a month, and consequently there will be a rush to lay in the winter supply once the strike seems to be on the way to settlement.

Coal Strikers Holding Firm

THERE has been so far no weakening on either side of the coal deadlock. The mine unions have been organized well enough to hold their forces pretty well in line and although one-third of the bituminous coal in this country is mined by non-union workers, the country cannot long tolerate the present union inactivity. Even if the strike should be ended immediately there would be a coal famine of no small dimensions this fall. Should the strike run through the sum-

mer, conditions will be actually very serious and will certainly damage industrial prosperity in a very direct manner.

The suggestion that factories purchase their winter requirements in advance at this time would do more harm than good, because it would simply accelerate the famine. The wise course is for everyone to protect himself for not more than two or three months and use every influence to have coal production resumed before the supply is exhausted.

Public opinion was apathetic about the mine strike up to the moment of the Herrin disaster. This miserable affair in Illinois has done the union's "reputation in men's eyes" good. The situation in this regard is well summed up by an editorial in the *New York Evening Post*:

"Not a word can be said in extenuation of the atrocities perpetrated at Herrin, Ill., by a mob of striking coal miners. It is the worst blot on the record of union labor in this country. Armed warfare in industrial disputes is bad enough, but what took place at Herrin was not war but massacre. There were apparently no casualties in the course of the actual 'battle.' Prisoners who had raised the white flag were shot down in Mexican bandit fashion. The blow is all the worse for labor because it implicates a body of workers who have hitherto conducted great strikes with perfect discipline. Only the other day President Lewis of the United Mine Workers took occasion to boast of his union's good record in this respect. And the blow is all the worse for labor because the blood-madness that seized upon the Herrin strikers seems to have been more than the ordinary wrath against professional strike-breakers. This time it was directed against a strike-breaking union. The fury was the fury of civil war.

"Yet for the very reason that a section of union labor which has hitherto acted with self-restraint has surrendered to the spirit of war without quarter the lesson of Herrin bears down on the conscience of the nation at large. The tragedy might have been averted if Government intervention had made itself felt in a strike that intervention could have settled. It has been a coal strike in which both sides have made knowingly impossible demands which called for an umpire and a decision that both sides would have accepted. The policy of letting the two sides fight it out has only brought about a startling demonstration of industrial warfare at its worst: on the one side, armed mobs and murder; on the other side, the professional strike-breaking agency; strike-breakers hired under false pretences, armed guards, and the power of the State seemingly acquiescent.

"The methods of industrial controversy must be civilized if we are not to have uprisings against civilization like that in Illinois."

Various newspapers place the blame for the outrage on the union miners, others on the operators and still others believe that the Federal Government is to blame. The *Brooklyn Daily Eagle* states the matter thus:

"The mine where the trouble occurred is an open one and does not require certified miners. Since the strike it has been operated under some kind of an agreement with the mine union officials, who permitted union men to get out coal for local consumption. It is charged that the mine owners broke this agreement and employed non-union men and members of the Steam Shovelmen's Union, which has been under the ban of the Federation of Labor. Incidentally, the mine owners are not members of the general operators' organization.

"All this is of minor importance, but it indicates quite clearly the chaotic conditions that led up to a wholesale murder that is a disgrace to the country. Running through the story are half a dozen organizations having to do with mining and the maintenance of law and order. The most amazing thing about the massacre is the utter complacency of everyone connected with these various agencies. At every turn we find men who are supposed to represent power, but no one has appeared who seems to represent responsibility.

"On one side there are the 'regular' mine union officials, headed by John L. Lewis. He had the power to call the mine strike and to decide that the Steam Shovelmen's Union was 'an outlaw organization' and that its members should be treated as 'common strike-breakers,' the law in this case being union law. Since the massacre Mr. Lewis has dropped out of sight and has had nothing to say. His responsibility apparently ended when he sent a telegram defining the status of the men working the mine. The status of most of these men has been much more definitely determined since Mr. Lewis sent his telegram. They are dead.

"The Federation of Labor, with Mr. Gompers at its head, is above the United Mine Workers. The Federation is in convention, making its own laws and attempting to make laws for the rest of the country, incidentally overturning the Supreme Court and the fundamentals of the Constitution. Yet the Federation and Mr. Gompers have done no more than 'deplore' the violence in Illinois and upbraid the operators.

"But there is lack of responsibility on the other side as well. The question whether the mine owners violated their agreement with the unions is important and should be thoroughly investigated. Also the details as to the employment of men who charge that conditions were misrepresented and the alleged use of a machine gun against strikers before they had attacked the mine. This, however, only leads up to the main fact that forty or fifty men have been brutally murdered."

Public Opinion Being Crystallized

THE trouble at Herrin, Ill., seems to be the climax of industrial disputes in this country and as the National Industrial Conference Board says in its *Weekly News Survey*:

"This industrial warfare . . . is rapidly crystallizing public opinion against labor disputes in general. While the number of disputes between employers and employees has been steadily decreasing during the last two years, it now has reached a total of somewhat over 100 per month as against a monthly average of 190 in 1921 and 370 in 1917.

"The Big Four Railroad Brotherhoods, representing the conductors, engineers, trainmen and firemen, and generally regarded as conservative unions, have been requested by the United Mine Workers of America at a joint meeting to agree not to transport coal from non-union mines with the expectation of further crippling the coal supply and forcing an early capitulation of the coal operators.

Textile Strikers Tiring?

THE *New York Sun* states that the textile strike in New England is having the effect of driving employees out of the district. Some 6000 skilled workers having left Rhode Island for Northwestern Canada and the Province of Quebec to engage in agriculture. But the textile strike is apparently wearing itself out. According to the *New York Journal of Commerce*, the ability of the strikers to hold out for so long a period can be attributed to the lack of unanimity among the manufacturers themselves. Throughout New England there are many plants that have held aloof from the struggle and are not following the Rhode Island mills in reducing wages 20%. New Bedford and Fall River are notable examples of this and none of the mills in these cities have as yet made any move toward falling in with the mills in the strike arrangements. With part of the mills reducing wages and part of them increasing from 48 to 54 hours per week and part of them continuing on the 48-hour basis, strikers have received the idea that a wide difference of opinion exists among the manufacturers and have derived from this idea not only moral support to continue but also have received large sums of money from sympathetic working employees.

With a condition of this sort existing, the strike will probably continue for some time to come, but it is certain to diminish in effect as mills go back into operation.

A Record of Strikes

ACCORDING to the National Industrial Conference Board the U. S. Bureau of Labor gives the number of strikes and lockouts since 1916 as:

	1916	1917	1918	1919	1920	1921
January	188	288	191	199	227	228
February	206	211	223	198	192	168
March	294	318	312	192	279	181
April	434	445	321	270	406	284
May	617	463	392	431	409	566
June	354	323	296	322	304	146
July	313	448	288	379	292	137
August	326	360	278	412	259	139
September	252	349	212	406	227	121
October	261	322	145	327	189	84
November	197	257	208	160	104	81
December	149	197	250	125	97	65
Month not stated	198	469	237	156	269	67
Total	3789	4450	3353	3577	3254	2267

Small Chance for Railroad Strike Success Shown Here

EXPORT • IMPORT

Exports in All Lines Improving

EXPORT trade with European countries continues to show an encouraging increase. In an article in the *Amerexa News*, the official organ of the American Export Association, H. H. Harvey states that the improvement in export business extends to nearly all lines. This opinion is based upon answers received from a questionnaire recently sent out to 1000 manufacturers embracing almost every line of industry. Replies were received from 75% of these manufacturers.

Over 85% of the answers portrayed a hopeful frame of mind, based on actual foreign inquiries or orders. Less than 15% of the replies displayed a pessimistic attitude. Fully 50% of the replies indicated a material improvement in the actual number of orders received, but all of the 85% of optimistic answers were based on a decided improvement in foreign interest in American goods. It is believed that subsequent months will show a continuance of this steady upturn. In regard to the credit situation the *Amerexa News* points out that while new facilities which have been developed in the last eight years for the financing of our foreign trade are not intended to provide credit where no basis for credit exists, they will enable existing credit to be utilized more fully, flexibly, surely and economically than heretofore. These facilities include:

1. Branches of American banks in foreign countries.
2. Foreign-trade banks with head offices in the United States and branches abroad.
3. The right of American banks to accept and the development of a discount market.
4. The readiness of our issuing houses and banks and of our investors to absorb immense quantities of foreign securities, creating an immense purchasing power here for export purposes.

Foreign Trade Financing

ACCORDING to the *Mid-Continent Banker*, the relation of the American banker to the work of securing and developing foreign trade is of outstanding importance. It is pointed out that foreign-trade financing is primarily a long-term credit proposition as contrasted with the short-term credits of domestic trading. Just as no banking system could have prevented the industrial depression of the world, no banking system can at once restore prosperity. Before the American banker can assist in restoring foreign trade there are some preliminary and absolutely essential things which must be done by Europe. Chief among these are (1) Political and social peace must be established in order that the normal processes of wealth creation can function. (2) Europe must abandon her wartime policies. This means not only a reduction in armies, navies, and other military expenditures, including repressive taxation, but also the wartime regulation of business, as well as the doles and other gratuities granted to the unemployed, or conceded to the employed as an unduly high wage. (3) There must be industry and saving, such as Europe has never known, in order

that a beginning can be made in solving the problems of balanced budgets, inflated currency and unstable exchanges.

The World Is Buying Motor Cars

A DEFINITE recovery in the automobile export business earlier than was at first thought possible is predicted by leaders of this industry. The value of April, 1922, exports are the highest since January, 1921, representing a figure a third to a half higher than many other months, and it is predicted that subsequent months will show a continuance of the steady upturn.

The imports of motor vehicles is increasing in Great Britain. The total number of passenger cars and trucks imported during the first quarter of 1922 was valued at \$461,328; and number of chassis 2370, value \$479,009. During the corresponding quarter of 1921 passenger cars and trucks imported amounted to 2914, valued at \$681,156; but imported chassis numbered only 963, valued at \$314,863.

Canada is reported to have ranked first as a source for the number of finished cars and fourth with respect to chassis. France ranked second with regard to both finished cars and chassis. Italy was third for finished cars and first for chassis, while the United States was fourth in finished cars and third in chassis. The automotive market is also said to be improving in Portugal, Syria, Peru, Brazil and Greece. In this last-named country American cars predominate, 65% of the cars being of American make.

Our Far Eastern Markets

THE determination of American exporters to find a market for their products is leading many of them to consider the trade possibilities offered by the Orient, particularly by Japan. Although exports from the United States to Japan are much less than in 1919 and 1920, there is a considerable gain over those of the pre-war period. The largest item in the list of American goods going to Japan is raw cotton, which in 1920 amounted to 339,000,000 yen. The next largest item in that year was 1,600,000,000 yen for semi-manufactures of iron bars, rods, plates, sheets, wires, pipes and tubes. Machinery and machine parts, autos, railway cars and parts, lumber and construction materials are among the other commodities that were bought in considerable quantities. In a recent issue of the *Editor and Publisher* it is pointed out that the tendency toward standardization along Western lines may be expected to increase the Japanese market for foreign goods.

As a result of the Washington Conference, the opportunities for trade with China have been greatly increased. Previous to the Conference American trade was handicapped in many ways, almost every other nation operating under so-called concessions which resulted in lesser import duties for their goods. Yet even under these conditions, during the two years following the war the United States had a substantial part in Chinese business, and it is believed that in the near future new markets for many products will be found in China.

Imports from Germany into New York customs district from Jan. 1, 1921, to March 31, 1922, by dollars—(Union Trust Co., Cleveland.)

ADVERTISING

Indirect Trade Marks

A GREAT deal has been written about the value of trade marks, the cumulative value acquired by year after year of consecutive insertions in magazines and newspapers. But little has been said about the indirect value of advertising style. Advertisers who for years have been employing a certain style of border, or peculiar type arrangement, or distinctive illustrative treatment have found that the indirect trade mark value is sometimes as great as that of the actual trade mark. The use of a peculiar style of border ties up a series in a way that cannot be accomplished by any other means; provides a link by which the reader may recognize any insertion as part of a series and forms as integral a part of the advertising campaign as does the copy itself. The use of some mark or method of treatment not only acquires a very definite trade mark value over a period of time, but in addition the reader will be influenced to purchase the product quite as much by the style as by the copy.

Style is generally recognized as the best method of obtaining that indefinable quality of atmosphere so much desired. It is evident that if any particular advertisement carries the impression of "atmosphere" which is needed to put across the campaign, a series run in the same style will work out much better than a number of different styles carrying different "atmospheric" impressions.

In the illustration at the foot of this page, the experienced advertising man or the casual reader of periodicals will have no difficulty in spotting the advertiser who uses the distinctive illustrative method shown in the first example.

There are perhaps a dozen collar advertisers using national mediums, but there are none whose copy could be confused with that of the well-known advertiser who uses the style shown below. The remarkable effect achieved by the peculiar border arrangement in the second example stamps the identity

of the advertiser upon the reader's mind quite as thoroughly as the trade mark.

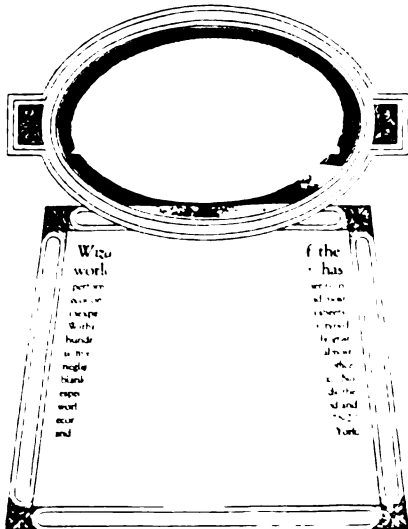

The automobile advertiser who uses the peculiar lettering in the third example has "registered" the copy to possible purchasers by newspaper and magazine copy as well as by periodicals and booklets. The style has value of its own.

How much weight does the style of your advertising carry? Cut out of your advertisement all reference to your product and see if those not particularly acquainted with your advertisement will instantly recognize it as your own. If not, there is probably something to be gained by adopting the method of indirectly trade-marking your goods.

How to Buy or Build a Mailing List

OCCASIONALLY the man who is conducting many mail-order campaigns for concerns in various lines of business runs into a situation where he finds himself in need of a mailing list of a certain class or type of people that can only be built, that cannot be bought. The weakness of most purchased mailing lists is that the names given are the firm names and not the names of individuals. Whether this weakness will affect the success of a campaign series addressed from the list depends upon the classification. If the narrowing down of the appeal will produce greater results the general list should be eliminated and a special list be bought or built. The following sources for mailing lists are suggested by Verneur Edmund Pratt in *The Mailbag*: (1) trade directories, phone books, rating registers; (2) mailing-list companies; (3) chambers of commerce (city, State, nation); (4) registration and license bureaus; (5) vital records (births, marriages, deaths); (6) house salesmen; (7) purchasing actual inquiry letters; (8) club, association and league membership lists; (9) clipping bureaus; (10) special and unusual sources.

AUTOMOTIVE

Automobile Production Records Broken

THE highest production record in the history of the automobile industry was reached in May, the output of 252,000 passenger cars and trucks exceeding the previous high mark by 32,000. It has been impossible to accumulate reserve stocks of passenger cars and all factories are now forcing production to keep pace with demand. The rapid pace at which cars have been manufactured has increased production costs. Shipments of parts by express, orders by telegraph and premiums for raw materials add to the expense of turning out motor vehicles on which the unit profit is much smaller than it was before the era of keen competition forced by business depression. However, this increase in production costs appears to have had a stabilizing effect on retail prices and few re-

visions are in prospect except in the truck field, where the return to normal conditions has not been completed.

The most popular topic of discussion within the industry, says *Automotive Industries*, is the outlook for the remainder of the year. There are reports from Detroit that some manufacturers contemplate keeping their plants running under heavy schedules late in the year to pile up stocks of cars in preparation for a 1923 demand which they expect will be larger than that of 1922. But it is pointed out that there is no reason to expect that sales of motor vehicles next year will be any larger than this, except in the great agricultural districts, and that the piling up of large inventories would be a dangerous expedient.

Is Engine Efficiency Increased by Overhead Camshafts? Technical article discussing the advantages and disadvantages of overhead camshafts (and of course, overhead valves), with special reference to efficiency in engine operation. Many splendid examples of American, British, German and Italian overhead arrangements are presented, and discussed, point by point. This is first instalment, consequently, author's conclusions are not presented, but he does point out that it gives (a) a more symmetrical engine, (b) greater accessibility, and (c) this type may be as quiet as another, and contrary to the general impression, is not inherently noisy. P. M. HELDT, *Automotive Industries*, 5-25-22, 5700 w. MAH.

Seven thousand people were killed at grade crossings in 1921.—*Tractor World*.

For Improved Electric Wiring for Automobiles. Author is sales manager for one of the most prominent manufacturers of electric wire and cable for automobile use, and hence, should be fully competent to discuss the subject. He takes up the types of cables and methods of installation used for ignition, starting and lighting circuits, and tells how these may be standardized within certain limits. He urges further standardization, and claims this would add

Estimated consumption of petroleum in the U. S., 1909-1921.—(*Magazine of Wall Street*.)

to the usefulness of existing S. A. E. standards for insulated cables. Others references are to splicing, terminals and other details. WILLIAM S. HAGGOTT, *Automotive Industries*, 5-11-22, 1850 w. MAH.

Nature of Intercity Motor Traffic. A series of thoughtful deductions from the results of the two road censuses taken by the Connecticut State Highway Dept., in co-operation with the U. S. Bureau of Public Roads. J. G. DOLITTLE, *Power Wagon*, 6-22, 3700 w. MAH.

Rail Cars and Motor Buses Make Good Showing. The showing was upon the occasion of the recent trip from New York to New Haven, over the tracks of the N. Y., N. H. & Hartford R. R. Co., and in one of that railroad's new Mack rail cars. Other members of the party traveled up by motor bus and a third section by regular railroad train. The test was in the nature of a comparison by the picked party of S. A. E. members of the three methods of comparison. The railcars made the trip in 2 hr. 40 mins., the buses in 3 hr. 22 mins., and the special express return train made it in an even 2 hr. Other details are given. *Motor Record*, 6-22, 1300 w. MAH.

"Thermos bottle" cars is an expression stating well the principle of the latest tank cars for the transportation of milk. The large glass-lined steel tanks are exteriorly like to the oil tank cars, which may be cleaned with hot water and soda. As the milk is chilled before it is pumped into the well insulated car, it arrives fresh at its destination.—*Steam Shovel and Dredge Mag.*

Tractor Gearset Has Novel Reverse Mechanism. Description of new design of gearset for tractors which embodies a radical departure. This consists of shifting the entire differential sideways, and this movement brings the gear ring on it into mesh with one or the other of two spur pinions, formed integral with the bevel gears on the intermediate shaft. A drawing is presented and the construction is described completely. *Automotive Industries*, 5-25-22, 450 w. MAH.

An aerial mail service has been established between London and Copenhagen, making it possible for mail posted in London in the evening to be delivered in Copenhagen on the afternoon of the following day.—*Steam Shovel and Dredge Mag.*

Commercial Aviation Development in U. S. Last of series on general subject of commercial aviation progress. In previous instalments, author has taken up in detail each of the principal countries of Europe and Asia, and has described past progress and present status of commercial aviation therein. In this article, apparently the conclusion, he takes up the U. S. in the same way. He predicts that U. S. will lead the world in this direction, within a few years, under certain conditions which he names. W. KNIGHT, *Aerial Age Weekly*, 6-5-22, 5800 w. MAH.

Proposed Air Traffic Law. Professor of the Paris College of Law lays down a series of fundamental laws based upon existing laws which deal with aerial traffic, and with such regulations as have been formulated by various countries. In addition much of this new legal code is anticipatory in nature, in that it is intended to deal with conditions which do not yet exist but are expected to in the near future. PROF. GEORGES RIPERT, *Aerial Age Weekly*, 6-12-22, 4900 w. MAH.

Regulation of Air Traffic. Author points out that present conditions show need for aerial laws, and proceeds to speak of many things which might be regulated by law, to advantage of all concerned. He refers to safety requirements, which deal largely with equipment and testing, with licenses, which deal mostly with the pilot's fitness both as a flyer and as a touring pilot, and with possible aerial traffic rules. DEVALUEZ, *Aerial Age Weekly*, 6-12-22, 1600 w. MAH.

Development of Wright Dirigible Engine for the Navy. Author tells how this new Wright engine, previously described in these columns, was developed for the use of the Navy in its dirigibles. Describes the designing, construction and testing of the engine. GEORGE J. MEAD, *Aerial Age Weekly*, 6-19-22, 2050 w. MAH.

Fighting insects with airplanes is the latest for saving trees. Trees too tall for pump and spray treatment were dusted with a poisonous powder dropped from flying airplanes. A short time afterward, literally millions of insects were found dead on the ground, only about one per cent escaping.—*Steam Shovel and Dredge Mag.*

Larson Tensiometer. Airplane wires must have a certain amount of tension to maintain the alignment of the machine, but this must not reach a dangerously high figure. This new instrument measures through the compression of a spring, the tension in the wire being

Estimated total sales in the commercial car industry for 1922. Estimated total \$1,010,000,000.—(The Chilton Co.)

measured. It is said that tensions can be read to 10 lbs., with only a slight correction due to the beam action of the short section of wire being tested. If proven practical, this simple device will prove wonderfully useful, and will save many lives. *Aerial Age Weekly*, 6-12-22, 1100 w. MAH.

English Fuel Report Shows Possibilities of Alcohol. This is a summary of the report of a sub-committee of the Empire Motor Fuels Committee (British). It shows the results of an extensive series of tests. In these tests it was found

that the thermal efficiency was nigher with alcohol than with gasoline at all speeds and under practically all conditions. Fuel consumption is higher if the engine is used without change but when changed to higher compression pressures is uniformly lower than with gasoline. Alcohol requires a greater spark advance but showed up equally well under all conditions of throttle variation. Furthermore, the engine ran more smoothly under alcohol. There were other conclusions, most of which seemed to favor alcohol. *Power Wagon*, 6-22, 2500 w. MAH.

New Airless Injection System for Oil Engines. In the Diesel type of engine highly compressed air is used to ignite the fuel which is sprayed in by means of a powerful pump. Some forms of the Diesel engine utilize the compressed air to force in the fuel. In all these engines various details of the air system have given trouble. This article describes the Hesselman engine in which no air is used for oil injection, a special flexible valve taking its place. Drawings of the complete valve, enlarged sketches of the principal spring element, power charts, and other interesting data are presented. EDVIN LUNDGREN, *Motor-ship*, 6-22, 3600 w. MAH.

A new biplane folds its wings, drops an extra pair of wheels, and proceeds like an automobile along the public highways. It hails from France.—*Steam Shovel and Dredge Mag.*

A comparison of the rate of increase of passenger and commercial-car registrations since 1913.—(The Chilton Co.)

BUILDING-CONSTRUCTION

Large Building Projects Economical

THE completion of plans by the Metropolitan Life Insurance Company for the construction of four square blocks of houses in Long Island is expected to have an important effect on the housing shortage, not only in New York City, but throughout the country. The maximum cost of these houses is \$6,500,000. There will be 50 houses of 39 apartments each, providing for a total of 1950 families in 8250 rooms. The apartments are to rent on the basis of not more than \$9 a room and have all modern improvements.

In the opinion of Mr. Stabler, the comptroller of the company, the housing problem in the higher-priced apartments in New York City will be solved by this fall. And it is hoped that the Metropolitan's plan may be adopted by builders of

low-rent houses in New York and other large cities. It is believed that speculative builders can put up such structures at a price even lower than estimated by the Metropolitan. The economies to be effected in the construction of these blocks of houses will result in many advantages to the tenants, not only in reduced rentals, but in added conveniences. Each house will occupy half of the lot. Every room is to be an outside room opening on the street, yard, or interior garden, and there will be cross ventilation in each apartment and separate staircases for each eight families. Each building will be isolated with interior garden, rear court and side passageway, developing to the full the principle of "block circulation."

Plea for Standardization in the Building Industry. Article by Government official on advantages following standardization and the elimination of varieties. JOHN M. GRIES, *Permanent Builder*, 6-22, 1000 w. CS.

Architectural Acoustics. Second installment of article on investigation made of methods for sound proofing three Federal Reserve Bank buildings. PAUL E. SABINE, *Amer. Architect*, 6-7-22, EMcC.

Small Units in House Building. Sixth article, covers roofs and tile walls. A. J. R. CURTIS, *Concrete*, 6-22, 1500 w. CS.

What Shall We Do with Our Clients? Covers relations of architect to client, with special reference to aesthetic values and community. IRVING F. MORROW, *Architect & Engineer*, 5-22, 1500 w. CS.

Tentative Minimum Requirements for Small-House Construction. Part I. Summary of preliminary government report on safe and economical construction. Covers walls of all kinds. *National Builder*, 6-22, 2000 w. CS.

Design Features of Lincoln Highway "Ideal Section." Covers committee discussion of "Ideal Section." Eighteen

principal points covered: width of right-of-way, pavement width, loadings, drainage, type of pavement, use tie steel, earth shoulders, lighting, curves, foot path, guard rails, crossings, wiring, advertising signs, obstructions to vision, markings, maintenance, comfort stations. W. G. THOMPSON, *Eng. News-Record*, 6-15-22, 6000 w. CS.

Painter's Judgment and the Building Manager's Specifications. Part III. Covers specifications for interior painting of office building. FRANK G. BREYER, *Bldgs. & Bldg. Management*, 6-12-22, 3500 w. CS.

About Highway Construction. Discussion on salaries for highway engineers, what has been done by various States on maintenance and construction of highways, and the need of new highways. A. R. HIRST, *Highway Engineer & Contractor*, 6-22, 1500 w. CS.

Field Check in Formulas for Earth Pressure. Results of measurements made to obtain information as to intensity and distribution of pressure exerted by saturated bank against vertical wall and especially what reduction in pressure would result from drainage under sheetpiles. H. S. SCHICK, *Eng. News-Record*, 6-15-22, 2500 w. CS.

Development in Method of Constructing Brick Pavements. Discussion of various types of brick and joint fillers. Recommends use lug brick with joints filled with asphalt cement. ARTHUR H. BLANCHARD, *Highway Engineer & Contractor*, 6-22, 1000 w. CS.

New Phase of the Shear Problem in Beams. Discussion of shear in beams, aiming to differentiate between end anchorage of rods that is thoroughly good and that which is "almost good." *Concrete*, 6-22, 1500 w. CS.

I-Beam Chart. Chart with graphic determination of safe load for a given span of I-beam of known weight and depth. Useful for engineering work. W. F. SCHAPHORST, *Iron Age*, 6-8-22, 350 w. APS.

Fireproof Qualities of Pressed Steel Construction. Analysis of pressed steel type of fireproof construction reveals following: Load carrying members are units composed of pressed steel joists made of highest grade and thoroughly worked steel similar to structural steel. These joists are covered with 2-in. concrete, and protected on under side with metal lath and plaster. This construction has satisfactorily passed several fire tests. A. H. BROMLEY, *Eng. World*, 6-22, 1500 w. CS.

Testing Caisson Foundations. Description of tests made on the site of the proposed Union Station in Chicago. The first time that such tests have been made. Full size concrete piers 65 feet deep were tested by loading and their carrying power was ascertained. The unique tests and the original method for applying the load are fully described. *American Architect*, 5-24-22, 1000 w. EMcC.

CLOTHING & GARMENTS

The Flapper's Influence on Trade

WILL there be "flappers" this fall? This question is being anxiously discussed in the clothing, millinery and hosiery trades. For not only does the presence of the "flapper" mean a demand for novelties, but an increase in the consumption of woolen apparel of all kinds. Last winter the cheap woolen "flapper" coat competed so successfully with fur that prices of fur coats were forced down considerably. In many quarters it is believed that this rivalry may continue during the coming winter. Recent developments in the woolen yarn

market, for example, seem to indicate a belief that the "flapper" will remain for some time to come.

Although worsted yarns are quoted in the local market at the same figure that ruled last week, prices for both weaving and knitting yarns are reported to be firm, and it is said that spinners are reluctant about booking much new business at current price levels. Yarn prices, according to authorities in the trade, are more likely to advance than to decline, and spinners are cautious in engaging for future deliveries.

Progress in Artificial Silk. Until present time artificial silk has only been produced of a count varying from eight to ten deniers, while double thread of silkworm is of two to three deniers. Complaint among consumers of artificial silk thread has been inability of manufacturers to place thread of fineness of natural silk on market. This need recently supplied by French inventor. By new method, same size of apertures may still be used and same maximum spinning speed of 45 metres per minute may be continued. Two factors of this improvement are: feed of viscose to each aperture in relation to unit of time and minimum percentage of acid in spinning bath. *Silk*, 5-22, 2200 w. HHH.

Artificial Silk Hosiery. Machinery and methods of manufacturing artificial silk hosiery. *WILLIAM DAVIS, Textile American*, 4-22, 3000 w. WRR.

Wet Cleaning and Bleaching. Continued article, first part considering equipment. Tubs may be of stationary type, of wood, cement or enameled iron. Three or four galvanized iron tubs of different sizes are always handy. Also need buckets, gallon-size enamelware or earthenware vessels, dippers and barrel for melted soap. Scouring table also essential, marble making best top, hardwood being next. Brushes are principal "tools" used by wet cleaner. Care should be used to secure proper kinds, as some may injure fabrics. Other equipment discussed include washer, extractor drying tumbler and steam board. *ROY DENNEY, National Cleaner and Dyer*, 5-22, 2400 w. CJW.

Shaded Goods. Among defects caused in finished fabric by scouring and steaming are what are known to trade as "shaded pieces." If this is caused by steaming, it is because piece receives more severe steaming in one part than another. Darker shade in that part receiving more severe steaming. May be caused by improper scouring, as when pieces are scoured too hot, or with too much alkali and this is not properly washed out. May, however, come from dyeing, due to fluctuating steam pressure, bringing pieces to boil too quickly, shading up with concentrated dyestuffs, etc. *T. J. BIERY, Am. Dyestuff Reporter*, 5-8-22, 750 w. CJW.

Making Embroideries and Venise Laces. Embroideries and venise laces made on

so-called schiffle embroidery machine. Embroideries stitched on respective cloth on which they are sold, venise laces stitched on silk cloth. Stitched cloth eventually dipped into chemical solution which burns out silk and leaves stitched design untouched. For this reason, venise laces also called burnt out laces. After designs for embroideries and laces are made next step is enlarging patterns or making cartons. On these cartons is indicated every stitch which machine will be required to make in order to reproduce design on cloth. Enlarged design on

Exports of artificial silk hosiery from Jan. 1, 1921, to Mar. 1, 1922.—(*Underwear and Hosiery Review*.)

carton six times that of original sketch. *Lace and Embroidery R.*, 5-22, 1800 w. HHH.

Rugs of Alpujarras. Rugs of Alpujarras, Spain, interesting both in process and design. Made of wool or silk, but basic fabric on which colored pattern is worked is hand-woven linen. Wool woven on this by passing strands through and under various threads of fabric. In some cases pattern has strong mosaic, angular and blocky in character; in others lines are freer and pattern is not so much controlled by weave of basic fabric. Evidence of strong Moorish influence in character of designs. *W. W. KENT, American Carpet and Upholstery R.*, 5-22, 2000 w. HHH.

When Should Retail Clothiers Advertise. Effective advertising campaign largely

dependent upon when various articles are advertised. Higher-priced merchandise should be advertised early in week, popular price goods toward end of week. Advertisements should conform to seasons. Feminine influence should be considered in planning Sunday advertisements. Sunday ads should follow up Saturday night display. *National Retail Clothier*, 5-22-2000 w. HHH.

How to Build Store That Sells. Building should be constructed with view to convenience for salesmen and trade. Use of glass showcases more advisable than shelves. All incoming merchandise should be carefully checked and marked in special department before being placed on sale. Surplus goods should be stored in wooden cases constructed to prevent damage by either dusts or moths. Store should be able to supply its own electricity in event of damage to regular lighting system. Display and stock cases should be prominently placed, but so arranged that broad aisles are possible throughout store. *National Retail Clothier*, 5-22, 2200 w. HHH.

Asbestos suits are made for persons engaged in work that requires fireproof clothing. Asbestos can be spun so fine that 100 yards of the filament will weigh only one ounce and cloth can be made from this weighing only a few ounces to the square yard.—*Steam Shovel and Dredge Mag.*

Card Clothing and Grinding. Carding is the chief state of cleaning wherein the minutest impurities ought to be removed. Faulty carding affects detrimentally all that follows after it. *W. R. HEWSON, Textiles*, 5-22, 900 w. MBB.

A paper tape measure is being rolled into German bolts of cloth. This permits the salesmen to tell at a glance the measure of cloth remaining in the bolt, thus economizing labor and time. The tape is marked off in yards and meters.—*Steam Shovel and Dredge Mag.*

DRUGS CHEMICALS

Furfural from Corn Cobs

THE production of the new furfural chemical compound promises to have a far-reaching effect upon industry, says the *Chemical Color and Oil Record*. Dr. Frederick B. La Farge and Gerald H. Mains, of the Bureau of Chemistry, are credited with having perfected methods for producing this compound from corn cobs. The most important results of the perfection of this process are that it will make possible the production of low-priced substitutes for a wide variety of hard rubber and synthetic resin products; provide a good market for waste farm by-products; conserve the native sup-

ply of methanol (wood alcohol) and the forest products, particularly hardwoods, used in the manufacture of methanol and provide a possible motor fuel supply.

Furfural, under the La Farge process, can be produced commercially for about 6 cents per pound, and with the development of the by-products, also obtained from corn cobs, it is believed that it may be produced even more cheaply. Among the available by-products are acetic acid and a gummy material which has a field of usefulness in the manufacture of coal briquettes.

Magnesium. Raw materials for manufacture of metallic magnesium are magnesite (carbonate) and magnesium chloride. Three processes proposed: Thermal, substitution and direct electrolytic. Practically all magnesium produced by electrolysis of chloride in state of fusion with or without admixture of sodium and potassium chlorides. Two processes for producing anhydrous magnesium chloride: action of chlorine on magnesium oxide and removal of water from chloride crystals. One process consists in drying in dry air at 150° for several hours and then exposing to current of dry hydrochloric acid at 300°C. Fusion point lowered by addition of other chloride and electrolysis carried out in two steps. Alloy of lead first formed. Chlorine disposed of by passing through towers containing milk of magnesia. Process consists of complete cycle and really consists in separation of magnesium and oxygen, in that, apart from production of byproduct potassium chloride, only raw material is magnesite. S. T. ALLEN, *Chem. Met. Eng.*, 5-24-22, 1500 w. CJW.

Sulfuric Acid. Description of contact plant built for U. S. at explosive plant C., Nitro, W. Va. Plan showed in 2 flow sheet. Contact mass calcined magnesium sulfate impregnated with platinum chloride, so that it contains 0.15% to 0.30% of catalyst. Combustion gases entering converter contain about 5.5% sulfur dioxide, balance consisting of oxygen and nitrogen. Conversion chart for determining percentage conversion of sulfur dioxide to trioxide from percentages of dioxide in entrance and exit gases and chart showing relation between strength of sulfuric acid and rise in temperature on dilution with water given. M. F. CHASE and F. E. PIERCE, *J. Ind. Eng. Chem.*, 6-22, 2500 w. CJW.

A powdered chemical compound is said to thaw frozen pipes more quickly than a blow torch. The powder, on being mixed with water, will generate a high degree of heat. The mixture is poured into the open end of the frozen pipe, and on meeting the obstruction will remove it by the heat, bubbling of gases, and the nature of the chemicals.—*Steam Shovel and Dredge Mag.*

Ammonium Nitrate. Description of modern practice and consideration affecting design and operation of ammonia stills, scrubbers, condensers, neutralizing tubs, evaporators and crystallizing kettles. If tar and sulphur content of ammonia liquor is as low as 0.01% and

0.05% can be neutralized directly with dilute nitric acid. Otherwise must be distilled. Product used in explosives, effecting considerable saving in cost and rendering explosive more suitable for many operations by reducing velocity of detonation to marked degree but increasing "heaving" effect, performing more useful work per pound of explosive. E. M. SYMMES, *Chem. Met. Eng.*, 6-7-22, 3500 w. CJW.

Phosphoric Acid. Study has been made of suitable methods for determining inorganic constituents of commercial phosphoric acid, which are given in outline. Tabulated results are given showing composition of different samples of phosphoric acid prepared from bones and from phosphate rock by sulfuric acid method and from phosphate rock by volatilization method. Volatilized acids are relatively low in such non-volatile constituents as calcium, iron, aluminum and manganese. Presence of other elements such as lead, sulfur, chlorine, and fluorine in unrefined acids depends more on contamination and on composition of rock or bones from which they are obtained than on process used in their preparation. Lowest proportion of inorganic constituents in samples analyzed was found in volatilized acid that had been collected in Cottrell precipitator and commercially refined. W. H. ROSS, C. B. DURGIN, and R. M. JONES, *J. Ind. Eng. Chem.*, 6-22, 5000 w. CJW.

Muscle Shoals and Nitrogen Supply. Nitrogen essential constituent of practically all explosives, and essential to all vegetable and animal life and required in number of important industries. Usually obtained in form of proteins, ammonia, nitrates or cyanides. Discussion of three processes for fixing nitrogen, arc, cyanamide and synthetic or Haber. At Muscle Shoals cyanamide process selected because of its dependability. General conditions of plant outlined, including power and raw material requirements and convenience with which these requirements can be supplied. Chemical reactions developed. Future of nitrogen fixation in U. S. will depend on relation between demand and supply of inorganic nitrogen. Estimated that total consumption in 1924 will be 294,500 tons, and 438,000 tons in 1930. Estimated domestic supply of by-product nitrogen estimated at 122,500 and 159,500 tons, respectively. Balance must be supplied by nitrogen-fixing plants. J. K. CLEMENT, *Chem. Age*, 5-22, 2500 w. CJW.

Indigo. General article on chemical and physical characteristics of indigo, extracts and modifications of same. Purpuric acid, or red extract of indigo, particularly mentioned. Commercial varieties of vary greatly in actual content of indigotin. Worst qualities are those of light blue color, approaching gray or green. Water should not exceed 85%. Ash should be less than 10%. Real indigo blue determined by titration with potassium permanganate. Various dye baths discussed. W. B. NANKSON, *Cotton*, 5-22, 3000 w. CJW.

Testing Dyes. Every lot of color should conform with recognized standard in strength, shade, tone, and other properties before delivery to user. Apparatus required for testing is enumerated. Two or three samples should be taken from different parts of lot and mixed. The material is weighted, made up to volume and various fabrics dyed and the products examined. Detailed directions for acid and chrome colors. E. GREENHALGH, *Am. Dyestuff Reporter*, 5-22-22, 1600 w. CJW.

Light Fastness of Dyestuffs. Outline of process based on discovery that dyes in solution are reduced in color value much more rapidly than on fabric, spectrophotometric analysis making possible study and detection of minute color changes, fact that different concentrations of dye have varying degree of perceptible color change, when faded; improved methods of regulating selectivity of wave-constituents of transmitted light (artificial daylight) and discovery of qualitative relation between absolute fastness and dyed fastness. H. S. BUSBY, *Textile Colorist*, 6-22, 1200 w. CJW.

Mordants and Mordanting. Chloride of lime is used to bleach vegetable fibres, and as discharge in printing calico; prepared by passing chlorine gas over thin layers of calcium hydrate, chlorine being absorbed, and desired article results. Ammonium chloride is employed in fixing aluminate of soda in cotton, and in dyeing aniline black. Magnesium chloride, very soluble substance, employed as addition to size for cotton warps. Alu-

ELECTRICITY

Boom Days Ahead for Hydro-Electric Power

THE present hydro-electric development of the country will be doubled if all the proposed 300 projects for which applications have been made to the federal power commission become available. These projects would add 20,000,000 hp. About one-quarter of the applications have been acted on by permit or license, representing 3,333,000 hp. for the installations approved. At an average cost of \$200 per horsepower, this would represent an ultimate expenditure of \$4,000,000,000 or an immediate expenditure of \$700,000,000.

Power points out that this development will result in im-

portant gains to the electrical industry. Not only will it benefit the makers of such equipment as enters into hydraulic plants and systems, but will increase the demand for competent engineers. The encouragement of federal supervision is being afforded impartially in all cases, whether they are small irrigation projects, or more important developments, such as that on the Boulder canyon of the Colorado river, or the Utah power and light development proposed for the Green river. It is believed the country will gain greatly by insistence upon sound engineering and financial conditions

Two-Stage Current Transformer. Brief discussion of the current transformer as used with measuring and controlling apparatus with special reference to the degree of accuracy which can be attained in the ratio and the phase angle. New type of current transformer is described in which it is possible to secure much higher accuracy with a given amount of copper and iron in the transformer. In new device the transformation is effected in two stages, the first yielding in the usual way a secondary current which is approximately correct in magnitude and phase, and the second yielding an auxiliary corrective current, which when combined with the first secondary current, gives a resulting current which very closely approximates the secondary current which would be furnished by an ideal current transformer having no errors. The two currents can be easily combined by having two like windings in the devices operated, one for the main and one for the auxiliary secondary current. The mathematical theory is developed and experimental curves are given to compare the performance of the new transformer with that of an ordinary simple current transformer of good average performance. H. B. BROOKS and F. C. HOLTZ, *J. Am. Inst. Elect. Engrs.*, 6-22, 7000 w. IG.

Parallel Operation of Commutating Pole Motors and Generators. Discussion of various conditions under which commutating pole motors are operated in parallel. Characteristics of machines, and division of load between generators are described. Vector diagrams are drawn. C. B. HATHAWAY, *Electric J.*, 6-22, 5000 w. IG.

Baltimore Oil Circuit Breaker Tests. Tests of large oil circuit breakers were made to determine the adequacy of oil circuit breakers for increased duty. Tests were made on 13,000 volts, 25-cycle power system. Largest generating capacity on tests amounts to 170,000 kw. Current obtained varied from 750 to 23,700 ruptured r.m.s. arc amperes. All tests were made by throwing three-phase metallic short circuits directly on the system which the breaker under test was called upon to clear immediately. Three oscillographs were utilized to record the sequence of events. Total of 200 short circuits was made directly on the Baltimore system without any breakdown whatever of the major equipment of the two operating companies,

and in all cases without causing any more than a momentary disturbance in the voltage in the system. Results indicate that it is possible with proper design to build oil circuit breakers which can be relied upon to satisfactorily interrupt large currents on high capacity systems many times in succession without damage to the breakers, without oil throw and without change of oil or adjustments. H. C. LOUIS and A. F. BANG, *J. Am. Inst. Elect. Engrs.*, 6-22, 6000 w. IG.

Economy in Central Stations Regarding Heat Equivalents. How heat and power are economized in central stations. Coal and power are synonymous and it is as necessary to watch one as the other. N. HARRISON, *Central Station*, 6-22, 4500 w. IG.

Determination of Motor Drive Power Requirements. Methods and apparatus for determination of motor drive power requirements of various machines. T. CROFT, *Electrical South*, 6-22, 5000 w. IG.

Small Current Consumers of Central Station Power. Use of power for various small installations. The relations of the power plant to these small consumers, etc., are discussed in general. N. HARRISON, *Central Station*, 5-22, 4000 w. IG.

Selection of Auxiliaries for Hydro-Electric Power Stations. Author tells of what auxiliaries consist, and then discusses each and its proper selection. He takes up central versus individual pumping systems for governor fluid, water versus oil for governor fluid, lubrication systems for waterwheel bearings, separate small waterwheels for auxiliary power supply, and other similar topics. F. H. ROGERS, *Power*, 5-16-22, 2700 w. MAH.

Dielectric Losses and Stresses in Relation to Cable Failures. Excluding cable failures due to lightning, external damage to the lead sheath and joint troubles, remaining transmission cable failures have been largely dielectric loss failures. Cables loaded with more current than they bear. Temperature readings should be made in conduits to indicate conditions that must be withstood by the insulation on the cables. D. W. ROPER, *J. Am. Inst. Elect. Engrs.*, 6-22, 6000 w. IG.

Pole and Cross-Arm Preservation. Length of life of telephone varies with

kinds of wood used, sizes of poles and service conditions. Decay of wood is result of fungi forms of plant life. Requirements for fungi growth are food, moisture and air. Poles set in gravel and broken stone are less likely to decay than those set in loam because they are likely to have a lower moisture content. Temperature is also important in fungi growth. Most favorable temperature varies from 60° to 90° F. It is not feasible to control the air supply nor the temperature and moisture. The food supply remains. Antiseptic agency used to poison the food supply so that fungi cannot live on it and die. Such an agent must be capable of being injected into the wood without being detrimental to the structure of the wood itself; it must not be poisonous to man and animals. It is also advisable to use a chemical which is insoluble in water. Coal tar products obtained from the distillation of coal tar are the best preservative met with in general practice. Wood should be dried before being treated as it absorbs more of the preservative in the dry condition. Costs of the brushing method of treatment are given. Dipping treatment ensures better penetration of the preservative into the wood. Other methods are also described as well as the process used in the impregnation of cross arms. Poles already in place can also be given a treatment with the coal tar preservative. E. E. KING, *Telephony*, 5-13-22, 6000 w. IG.

Magnetic Clutches in the Cement Industry. These devices are used to transmit up to 600 to 800 HP. Torque requirements are discussed, and operation of magnetic clutch in tube mill is described. Magnetic clutches possess advantage over other types because force required for operation is developed within clutch structure itself in place of being transmitted from outside source by means of sliding collars, toggles, etc. Simplicity of mechanism is one of main characteristics of magnetic clutch. Highly desirable to use clutch which may be operated simply by closing switch, as contrasted with mechanical clutch which may require one or several men to engage it. W. H. COSTELLO, *Cement, Mill and Quarry*, 6-5-22, 2000 w. IG.

Application of Relays. Detailed discussion of operation of relays; Vector analysis is used. L. A. TERVEN, *Electric J.*, 6-22, 5000 w. IG.

Highway Lighting a Factor in National Development. This article is in the sense of a message to the electric lighting industry of the country. The need for adequate service to the farmer is emphasized. Importance of good highways is indicated. Proper lighting of these highways is shown to be an important factor in the development of industry and in getting produce to market from the farm and in the inter-urban movement of merchandise by motor trucks. R. TRAUTSCHOLD, *Central Station*, 5-22, 6000 w. IG.

Residence Lighting. Importance of proper lighting of residences is emphasized. Three systems are in general use, that is, by direct, or semi-indirect or totally indirect illumination. Lighting of each room in house is described. A. L. POWELL and H. A. SMITH, *Electrical South*, 6-22, 8000 w. IG.

Electricity in the House. Sixth of series of articles, this one dealing with cellar of modern house. Writer shows it to be sensible and economical to pay as much attention to wiring of cellars as to wiring other rooms. M. O. WHITTON, *Amer. Architect*, 6-7-22, 1600 w. E. McC.

A monster searchlight will now illumine the skies ten miles above the earth. This light may be used as an airplane guide at night and also for advertising purposes. Letters of light on the clouds—what a possibility for an advertising agency!—*Steam Shovel and Dredge Mag.*

R. R. Telegraph and Telephone Practice. In this article the effects of resistance, inductance and capacity on line circuits and in cables are discussed. B. STANLEY RHODES, *Railway Signal Eng.*, 5-22, 6000 w. IG.

Application of Telephone Repeater. Description of technical difficulties that are in way of general application of telephone repeater. Need for large amount of auxiliary apparatus is emphasized. Various examples of interesting uses of telephone receiver are cited. H. S. OSBORN, *Telephony*, 6-3-22, 5000 w. IG.

Analogies Between Telephone and Animal Ear and Vocal Organs. An interesting discussion showing relation between ear and vocal organs and telephone. It is indicated that the hearing and speaking functions of the telephone are inseparable. Comparison of telephone and ear alone is incomplete. Such comparison is perfect only when vocal or sound producing organs, as associated with the ear, are included in discussion. T. W. LOCKWOOD, *Telegraph and Telephone Age*, 5-16-22, 2500 w. IG.

Minimum Stress Theory of Cable Break-downs. It is proven that the maximum stress theory is incorrect. D. W. SIMONS, *J. Am. Inst. Elect. Engrs.*, 6-22, 6000 w. IG.

Simple Home Made Radio Receiving Set. Instructions in detail relative to the making of the various parts of a radio receiving set and manner of installing them. *Radio*, 5-22, 6500 w. IG.

Effect of irradiation in reducing legibility of high-wattage electric signs on clear nights. The upper series of letters shows the appearance of an illuminated electric sign letter of various distances ($H = 10$ ft., fifteen 75-watt clear lamps in vertical stroke). The lower series shows the same letters as seen by daylight when the effect of irradiation is negligible. At 5000 ft. for the lighted letter and at 11,500 ft. for the daylight letter, the space between the strokes is about one minute of arc and the letter is at the limit of legibility. The true effect from the illustration can be best obtained by holding the page at such a distance that the smallest E in the lower row is legible.—(McGraw-Hill Industrial Letter.)

Radio Installation Rule Division. A number of tentative rules for the installation of radio equipment as devised by the special committee of the National Fire Protection Association. *Telephony*, 6-3-22, 2500 w. IG.

Practical Device for Radio Reception. Description of a vacuum tube device which does not require a storage battery but which will give comparable results for radio reception. *Electrical South*, 4-22, 2000 w. IG.

Radio Limited. Description of special train equipped with radio sending and receiving apparatus, both telephone and telegraph. J. J. GRAF, *Railway Signal Eng.*, 5-22, 2000 w. IG.

A radio telephone at each of the 70 tables of a San Francisco hotel enables the diners to listen to one of several concerts that are broadcast daily. Diners now eat while listening and the hotels of the city are making preparations to have wireless phones installed in their guest rooms.

Braking with Direct Current Motors. Direct-current motors may be made to develop braking action under two conditions—one when load drives armature above normal speed; second, when motor is disconnected from line and its armature circuit is closed through resistance. First is called regenerative braking and latter dynamic braking. Article describes how actions take place and how they are applied to operation of direct-current elevator motors. B. A. BRIGGS, *Power*, 6-13-22, 1000 w. CJW.

Electrification of Steel Mills. The general effect on the operations, the advantages of central power plants are discussed. The effect on production was shown to be very advantageous; in some cases the increased output of the mills has amounted to 5% to 10% when elec-

tricity was used to drive them. Motors are very effective in driving reserving mills. Operating labor cost is less. Maintenance and repairs are less. W. SYKES, *Iron Age*, 6-1-22, 4500 w. IG.

Electrodes. Outline of process of manufacture of continuous electrodes at furnace. Various installations described. Advantages over carbon electrodes are: Reduced cost, cost of special mounting and protecting against air corrosion avoided, baking done without cost (by waste heat), electrode consumption is reduced, running of furnace is more regular, individual plants independent of electrode factories, number of laborers can generally be reduced and working conditions improved, and possible to make new furnace construction, which opens up possibilities for further development in smelting industry. C. W. SODERBERG and M. SEM, *Chem. Met. Eng.*, 6-21-22, 3000 w. CJW.

The telephone systems of the United States comprise 34,000,000 miles of wire.—*American Lumberman*.

Vulcanized Fiber. Discussion of various properties of hard or vulcanized fiber, as used for electrical insulation, including surface resistance, dielectric constant, resistance to heat, absorption of moisture, and resistance to moisture. RETZOW, *Paper Trade J.*, 5-25-22, 2500 w. CJW.

It is estimated that 19,000,000,000 telephone messages are transmitted annually in the United States.—*American Lumberman*.

FUEL POWER

Heavy Imports of British Coal Doubtful

THAT the fuel shortage, in the event of a lengthy coal strike, will not be relieved to any great extent by British coal is evident when the cost of shipping it across the Atlantic is considered. British producers and shippers assert that unless all their coal can be brought over as ballast, it is useless to expect more than occasional shipments. The full cargo rate of \$4 a ton on Welsh coal, and the charges for insurance, stevedoring, lightering, etc., added to the New Castle price of \$4.83 would bring the cost of the British product to about \$10 a ton, whereas the American price at Hampton Roads is only \$6.10 to \$6.50 a ton.

Referring to the cargo of bunker coal being brought to this country on the *Watsness*, a prominent exporter is quoted by the *Wall Street Journal* as saying that "recent fixtures at

ballast rate cannot be taken as an indication that any great movement will go at this rate. As soon as orders materialize to an extent the necessity would force fixing a charter at regular full-cargo freight rates. The fixture of 8s 6d on the *Watsness* ballast cargo was made for the purpose of bringing the vessel to the United States at cost. Otherwise it would be forced to come with sand ballast, which would mean no return to the steamship company. Probable rate on fixtures in the future will be near \$4 a ton."

It is pointed out that if the British price were to decrease \$2 or more a ton, or if the American price were to go above \$9 a ton, no doubt there would be a good market for British coal. The former, however, is regarded as impossible, and Secretary Hoover will prevent the latter if it is exorbitant.

Calls Present-day Waste of Coal in U. S. Criminal. About 95% of coal used is wasted so far as effective work is concerned. Average yearly coal bill in America amounts to \$27 per person. Smoke costs untold millions annually. Railroad electrification would reduce fuel bill of transportation lines 64%. Gives facts regarding smoke menace to health, and statistics of smoke costs along various lines. *Bldgs. & Bldg. Management*, 5-1-22, 1200 w. CS.

Liquid Purification. Report of investigation of two systems: Seaboard, in which gas is washed by circulation of sodium carbonate solution and liquid fouled thereby revived by spraying down acidifying tower through which air is blown; and O'Neill, in which gas is washed by circulation of treated weak ammonia liquor and fouled liquor passed through treating tower or still for driving off contained hydrogen sulphide and carbon dioxide. Neither system has as yet proved to be very efficient as total sulphur removers, but both are very efficient cyanide removers. Both types claim very large sulphur absorption in their oxide boxes placed after liquid system. Results of test runs on each type. A. M. BEEBE, *Gas Age-Record*, 6-17-22, 1600 w. CJW.

Anthracite Briquetting in Canada. Near London, Ont., a company is successfully briquetting anthracite fines with crude oil residuum. Article describes the process, equipment, product, use of same, etc. Important point is cooling and hardening of briquettes, by means of a special device, and this is described in some detail; also illustrated. *Mechanical Engineering*, 5-22, 1350 w. MAH.

Bark as Fuel. Brief résumé of literature. Average bark from slasher and drum barkers (dry) has 8,660 BTU per lb. Various methods of drying bark are reported. E. R. SCHAFER, *Paper Trade J.*, 5-25-22, 1000 w. CJW.

Chloridizing Volatilization. Fuel consumption appears crucial point in commercial application of process. Depends chiefly on tonnage, draft and radiation. In its present form, Bureau of Mines

process (Mining and Scientific Press, Aug. 27, 1921) will hardly compete with other processes except in localities where fuel is unusually cheap. Next problem consists in determining to what extent fuel consumption can be reduced by suitable modification of furnace. R. GAHL, *Eng. Min. J.-Press*, 6-3-22, 1200 w. CJW.

Fuel Oil Viscosimeters. Account of standardization and calibration of American-type of viscometer, known as Saybolt furol, and conversion tables for Saybolt furol, Admiralty and Universal instruments. W. H. HERSCHEL, *Chem. Met. Eng.*, 6-21-22, 1500 w. CJW.

Coal and Oil Burning Boilers. Results given show that in small plant producing about 4000 lb. steam per hr. for period of 10 hrs. daily, oil can be burned as economically as coal. If load fluctuation is considerable, there may be substantial saving by use of fuel oil. S. A. SMITH, *Power*, 6-13-22, 750 w. CJW.

Some Notes on Gas and Oil Turbines. Author tells why there are no commercial turbines despite a number of experimental forms. He claims the pre-cooling used in many types is really a modification of the Otto cycle, and that it prevents success. Another point on which he lays considerable stress is that steam turbine has steady stream of fluid against blades, which in gas turbine there are long intervals between

gas impulses against blades. This intermittent action he claims causes excessive wear of the blades, which means frequent overhauling and time lost, consequently failure. MAX SCHUELE, *Power House*, 5-5-22, 1560 w. MAH.

Machine Firing Lowers Fuel and Labor Costs. Description of machine that mechanically and constantly feeds coal into fire boxes of either round or rectangular kilns at any rate desired and any quantity for each furnace for use in pottery or heavy clay products manufacture. *Brick and Clay Record*, 6-13-22, 1000 w. CS.

Steam Pipe Losses at High Temperatures. Besides describing recent experiments on losses from bare steam piping, author presents large chart for reading off losses directly, knowing length of exposed pipe, its size, gage of steam pressure, and its temperature. R. H. HEILMAN, *Power*, 5-16-22, 550 w. MAH.

New Method Proposed of Arriving at Heat Losses Due to Wind. Suggested method based on Weather Bureau records of wind velocities and directions during cold spells over period three years. H. M. HART, *Heating & Ventilating Mag.*, 6-22, 500 w. CS.

Steam Waste in Heating Railroad Coaches. Covers typical temperature regulation system, comparison of series and multiple arrangement of radiating pipes, economy of thermostatic regulation. T. W. REYNOLDS, *Heating & Ventilating Mag.*, 6-22, 3000 w. CS.

Sanitation, Heating and Lighting of Suburban and Country Houses. Part VII. Covers bathrooms: materials and fixtures. EDWARD E. ASHLEY, *National Builder*, 6-22, 2000 w. CS.

Refrigeration. Function of expansion valve is to pass ammonia at high pressure through small opening into low-pressure side of system, decreasing pressure from 125-175 lbs. to 15-25 lbs. Direct expansion and brine systems of cooling are briefly described and tables of salt solutions given. T. H. FENNER, *Power House*, 6-5-22, 1500 w. CJW.

Growth of coal production since 1880.
—(Power Plant Engineering.)

Solving a Difficult Heating Problem. Account of improvements effected in steam producing plant of Transportation Building, Chicago. Has 40,000 feet single glass window area, is long, high, narrow structure with four sides fully exposed to elements. *Bldgs. & Bldg. Management*, 6-12-22, 2000 w. CS.

Centralized Combustion Control for Boilers. Instead of usual individual controls for each unit, New York firm has developed equipment for automatically controlling bank of boilers from single, small master controlled. Regulating system, which is described in detail in this article, is designed to maintain constant character of combustion at all loads on boilers. *Power*, 5-16-22, 2900 w. MAH.

Exhaust Energy in Reciprocating Engines. Surprising number of cases where oil, gas or steam engines will show better economy than purchased power and electric motors, and this may be emphasized where exhaust from steam engine is valuable for heating or process work. Up to now reciprocating engines have suffered from losses due to incomplete expansion. There has been compromise between such losses and mechanical ones connected with use of very large cylinders. Oil engines, multiple expansion and uniflow steam engines are coming to use high rates of expansion, and these are doing much to reduce exhaust losses. Many advantages may be gained, however, if energy remaining in exhaust at release can be converted into kinetic energy and from that into partial vacuum in cylinder. Theoretical problems are presented and practical applications to either single- or multi-cylinder engines are suggested and illustrated. J. STUMPF and C. C. TRUMP, *Mech. Eng.*, 6-22, 2000 w. CJW.

Comparative Advantages of Unit and Line Drive in Industry. Installations in various industrial plants, such as paper mills, sugar refineries, mills are discussed. Individual conditions in each plant should be taken into consideration in determining whether machines should be driven by individual motors or from line shaft. Character of work, cost of installation and operation, and its bearing on production costs and effect on quality and quantity of output must be considered. Figures show comparative costs of two methods of driving machines. Each type has its advantages and is best used for certain purposes. Neither type superior in all cases. Advantage usually found in favor of group drive in connection with lighter machinery, such as in textile mills, canneries, can factories, etc. Paper making a problem in close speed control, and line shafts are often advantageous in paper mills. Individual drives are best suited for heavy work. H. P. PHILLIPS, JR., *Elect. and West. Ind.*, 6-1-22, 2500 w. IG.

Automatic Boiler Rooms. Customary operation of industrial plant's boiler room constitutes paradox. It is department subject to inflexible rules, commonly operated loosely and without exactness. It will continue to serve as an exceptional example of inefficiency until it is made automatic. Almost everything in boiler room is essentially automatic in nature and usually manual

in practice. Automatic boiler rooms will sell power cheaply, at profit, to disgruntled operators of manual boiler rooms until this condition is corrected by education of industrial executives. *Industrial Power*, 6-22, 750 w. CJW.

After-cooling in Air Compression. Chief function of after-cooler is to remove moisture, which, if permitted to remain, ultimately reaches pneumatic tools and has harmful effects. Also liable to freeze in valve ports, etc., making tool sluggish in action and greatly retarding production. Use of after-cooler may actually increase power required to deliver foot of compressed air to tools, but over-all efficiency of tools, men and plant will be higher. Other advantages are that there will be less expansion and contraction of pipe lines, smaller pipe lines, reduction of expansion strains in pipe lines, removal of oil and tar from air and lessened risk of receiver explosions. P. A. BAUMEISTER, *Power*, 6-13-22, 1200 w. CJW.

Putting Steam Turbines in Service. Article actually refers to process of starting up, which is one always dreaded by engineer of very large units, and as this article is mainly about large units, this is logical. Turbines are referred to more than engines, although act of warming up and then cutting in tandem-compound unit consisting of high and low pressure cylinders in line and coupled up, is described. Types of turbines referred to are illustrated and described. *Power*, 5-16-22, 3400 w. MAH.

Refrigeration for Power Plant Engineer. General principles of the ammonia compression system are presented in this article, which is the third of a series. The properties which make ammonia a good refrigerating medium are explained, as are also carbon dioxide, and others. System is illustrated and described in some detail for power plant engineers. T. H. FENNER, *Power House*, 5-5-22, 4600 w. MAH.

Maintaining Heat Balance at Hell Gate. In this plant all auxiliaries are electrically driven by 60-cycle alternating current motors. What is referred to as heat balance is arrangement and control of apparatus in heat cycle to secure operations with least possible waste of heat. Incidentally possible disturbances and disturbing factors must be considered, as well as continuity, for nothing should be done in search for economy which might increase possibility of shut-down or make it more serious. From these view-points, all equipment and apparatus in this plant is considered. *Power*, 5-16-22, 3050 w. MAH.

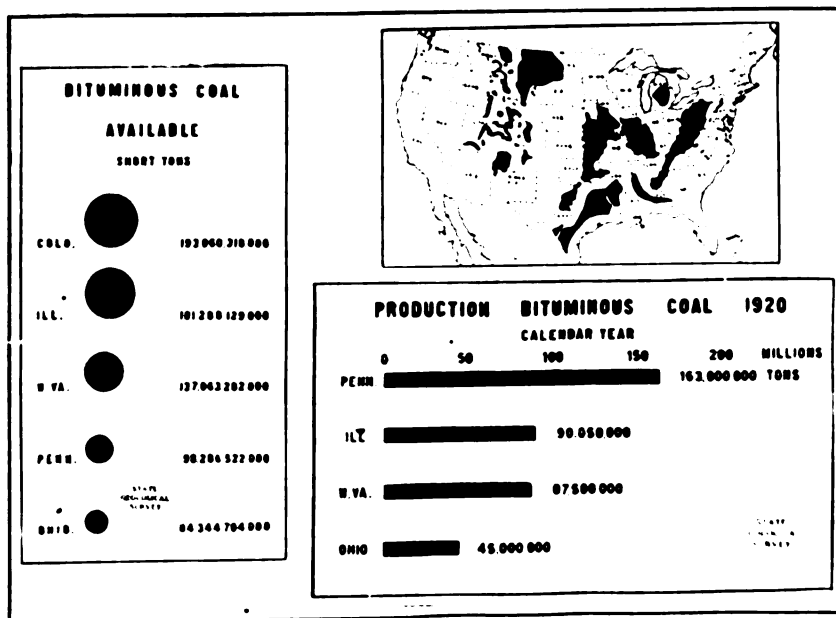

Value of Rope. Purchaser of rope is in need of education as to its possibilities. When rope once passes from warehouse of maker to custody of user, greatest abuse and most wasteful neglect seems often to be its portion. Reputation of rope-maker may be ruined through improper stowage and careless use. Endurance test should be uniform. Might use falling weight through determined distance. Should be tested both dry and wet. Tables should be tested for resistance against abrasion. Question of standard lay also important. FELIX RIESENBERG, *Cord Age*, 5-22, 800 w. CJW.

IRON STEEL

Iron Ore Prices

A REDUCTION in price of Lake Superior iron ores of 50 cents per ton is unfortunately without effect on pig iron prices, as an actual advance of several dollars per ton has been registered in the latter due to scarcity of coke on account of the coal strike. This decrease results partly from lower freight costs and partly from the light demand.

The most important ore from the tonnage standpoint is Mesabi non-bessemer. The season prices (f. o. b. Erie docks) have been:

1915....	\$2.80 per ton	1919....	\$5.55 per ton
1916....	3.55 " "	1920....	6.55 " "
1917....	5.05 " "	1921....	5.55 " "
1918....	5.05-5.75 per ton	1922....	5.05 " "

The price now developed is back to the 1917 basis and probably indicates lower prices on pig iron, which will, however, materialize only after the coal situation is adjusted and coke prices become normal.

Electric Cast Iron. History of electric cast iron, problems of cast iron, basic and acid bottoms in electric cast iron furnaces, given at Baltimore meeting of American Electrochemical Society. Great reduction in sulfur and improvement in castings. Complete tables of costs from German operating data. Electric pig iron from the ore. Four papers with discussions. *Iron Age*, 5-4-22, 4000 w. APS.

Electric Iron and Steel from Same Furnace. Alaska Treadwell Gold Mining Co. has been manufacturing electric iron castings since 1918. For perhaps seven months in the year, this company has surplus of electric power generated in its hydroelectric plants. When Connells-ville coke is \$8 at Atlantic Coast, it costs this company \$48 delivered. Foundry pig is similarly expensive. As a result of these conditions—cheap electric power, high coke and pig costs—this company has been able to produce iron in the electric furnace from an all-machinery scrap without use of pig. It has found, too, that the same furnace could be used for making steel by simply alternating the two, the only necessity being that the furnace must be completely drained of iron. Details of process are given, especial attention being paid to many important departures from usual cupola practice. W. E. CAHILL, *Iron Age*, 5-11-22, 1900 w. MAH.

Control of Silicon in Blast Furnace. How composition of iron is regulated by varying composition in general of the charge and by controlling hearth temperature. Critical temperature for reduction of silica to silicon is 1450° C., which exists only in hearth. Large amount of slagging bases tends to prevent silicon forming. More silica in charge tends to result in more silicon in iron. Higher temperature in hearth leads to higher silicon in iron. S. L. GOODALE, *Blast Furnace & Steel Plant*, 5-22, 5000 w. APS.

Shaft and Open-Top Furnaces. Electric smelting of iron ore brings into consideration certain features of furnace design which are peculiarly applicable to this art. Discussion of two types, stack and open top. In former, variable operating conditions are caused by segregation and variable electrical conduction by irregular settlement of charge and after molten metal is tapped from furnace.

Open-top furnace permits operation of be more closely controlled because variations in smelting rate show in conditions at top of charge. Stress is laid on advantage of placing charge just where it is wanted with assurance that it will not be segregated. Initial cost of construction is lowest and cost of maintenance is also lowest. R. C. GOSROW, *Trans. Am. Electrochem. Soc.*, 1922, 12 pp. *Chem. Met. Eng.*, 5-3-22. CJW.

Blast Meter in Foundry Practice. Necessity for measurement of air blast volume in cupola control with description of measuring instruments. LOUIS L. VAYDA, *Iron Age*, 6-8-22, 1200 w. APS.

Buckets and Skips for Blast Furnaces. Discussion of relative values of these two systems of filling. Reference made to actual plant practice in this country and abroad. Discussion. D. E. ROBERTS, *Iron Age*, 6-8-22, 3000 w. APS.

Economics of British Blast Furnace Practice. Presidential address before annual meeting of Iron and Steel Institute (London) took up possibility of relaxing chemical specifications if mechan-

ical are met; the possibility of change in mixer practice to utilize a broader range of ores. Cost of modernizing an existing plant. British blast furnace capacity is 17,000,000 tons annually, restricted to 13,728,000 tons by blowing power, maximum output 10,260,315 tons in 1913; actual output 8,034,700 tons in 1920. Problems in improvement of old plant. Problems in ore supply and ore handling. *Iron Age*, 5-25-22, 4000 w. APS.

Metal for Cast-Iron Wheels. Three distinct compositions embodied in one mass: white, gray and mottled. Care necessary in blending cupola charges. Analysis of mixture. Features of pouring, annealing and cooling. Y. A. DYER, *Iron Age*, 6-1-22, 3500 w. APS.

Steel for Forge Welding. Method of manufacture, composition, fluxing quality, susceptibility to heat and welding temperature as they affect welding quality of steel. Average results of 80 tests on forge welds of hammer-welded pipe compared with original material. Steels not over 0.15 carbon and minimum tensile strength of 47,000 lbs. or not over 0.20 carbon and minimum tensile strength of 52,000 lbs. are satisfactory for forge welding pipe lines, penstocks, tank-car work, etc. Most important considerations for uniformly good work are suitable material, expert operators and facilities for control of operation. FRANK H. SPELLER, *Blast Furnace & Steel Plant*, 5-22, 2400 w. APS.

An Adaptable Electric Steel Co. Has two plants for forgings with various-sized furnaces, thus making economical operations possible, as each plant handles that kind of work which it is best fitted for. Photographs of operations especially good. SIDNEY G. KOON, *Iron Age*, 5-4-22, 2000 w. APS.

Direct Method of Steel Manufacture. Speculation and research on this problem has continued for 50 years. Discussion of Bourcoud process. Reduction of ore is by gases (as in other cases) and new gas producer is developed, using coal, lignite, coal and peat mixtures, oil, tar, natural gas, etc. The efficient application of the gases. Outline of process is given, and the estimated economical results, leading to the conclusion that such a direct process has possibilities not only in those localities

Iron and steel, as industrial barometer, show substantial and continued improvement. Indexes are based on a value of 100 for 1913.—(System.)

possessing natural resources of iron ore and fuel unsuitable for use with present methods of manufacture, but even in the districts where today the bulk of our iron and steel is produced. A. E. BOURCOURD, *Iron Age*, 5-18-22, 2800 w. APS.

Leaves from Steel Melter's Notebook. Part 4. Practice in open-hearth steel furnace when natural gas was used for heating and melting. Details of furnace construction. Air supply was insufficient and fan was used to overcome difficulty. Air volume calculations. HENRY D. HIBBARD, *Iron Age*, 5-4-22, 2000 w. APS.

Accuracy in Temperature Measurements. Accuracy is essential because of variations in the steel. Effect of errors in instruments. Potentiometer pyrometer is recommended. Method of cold junction compensation by resistance coil. Remarks on thermocouples with reference to standardization. Noble metal thermocouples calibrated by Bureau of Standards should be used for reference. HORACE C. KNERR, *Forging & Heat Treating*, 5-22, 3000 w. APS.

Corrosion. Attention is called to type of electrolytic corrosion due to action of electrolytic cells which corrode metals in certain anodic areas, position of these areas and electromotive force of cell being governed by differences in concentration of substances dissolved in corroding solution. Of interest in connection with pickling of steel. R. J. McKAY, *Trans. Am. Electrochem. Soc.*, 1922, 10 pp. CJW.

Carbonizing Process. Relation of time and temperature to depth of case. THEODORE G. SELLECK, *Amer. Soc. for Steel Treating*, 5-22, 3000 w. APS.

Acid Open Hearth Steels. Discussion of underlying principles and necessary furnace practice for production of high-grade nickel steel for gun tubes and shafting. Comparison of pig, scrap and ore process used in America with all-scrap process used in Europe. Steel should be brought at moment of teeming to desired composition in every respect. Temperature must be accurately regulated. Retention of inclusions must be restrained by deoxidizing molten metal as fully as possible by means of carbon or pig iron, because product of its oxidation is gaseous and escapes, whereas those of all other deoxidizing agents are solid or molten and tend to remain as inclusions. Nearly complete deoxidation by carbon should be followed by further deoxidation by silicon. Manganese should not be added until after this silicon has done its work of deoxidation, in order that as little as possible of it may oxidize. Steel should be held in ladle moderate length of time to allow inclusions to rise to surface and also for much more important purpose of permitting finished steel to fall to proper temperature for casting into successful ingot. Furnace hearth should be protected from iron oxide by covering it, before charging scrap, with about half of pig iron used. W. P. BARBA and H. M. HOWE, *Chem. Met. Eng.*, 5-17-22, 2000 w. CJW.

Effect of Sulfur on Rivet Steel. Results of large number of tests by joint com-

The upright columns represent pig iron production each year from 1860 to 1922. The 100 line shows normal output, and the heights of the columns indicate the percentage by which actual output was greater or smaller than normal. The dotted line shows interest rates on commercial paper, multiplied by 10. Cross-hatched columns show years of depression.—(Leonard P. Ayres, vice-president, Cleveland Trust Co.)

mittee on investigation of phosphorus and sulfur in steel, shown mostly in form of curves. Sulfur up to 0.1% in well-made rivets does not affect hot or cold shortness, practically no effect on tensile properties, little effect on elongation; an unmistakable deterioration in impact strength is noted above 0.06% sulfur, which is accelerated by annealing. There is practically no effect on hardness of torsional properties. Static strength of rivets in single or double shear is closely approximated by shearing strength of rivet bar, and equals 38,200 lbs. per sq. in. for basic open-hearth steel containing 0.11 C., 0.43 Mn., 0.01 P. and 0.03 S. Each 0.01% sulfur decreases this value 300 lbs. per sq. in. The maximum sulfur now allowed in structural steel rivets (0.045%) is at least 0.01% below point where sulfur will damage strength of well-made rivet steel, as far as its performance can be predicted by known tests. E. E. THUM, *Chem. Met. Eng.*, 5-31-22, 1800 w. 15 curves. CJW.

Identifying Special Steels. Description of new French method, and apparatus included in it, for identifying special steels thermoelectrically. The process has been devised and perfected by M. Galibourg, and is based upon utilization of electromotive forces of contact. No special treatment of the steel is necessary, nor does heat treatment or other processing change the results greatly. A number of materials have been tested, and charts have been plotted for them. *Iron Age* (translation from *LeGenie Civil*), 5-11-22, 880 w. MAH.

Brands vs. Analysis in Buying Tool Steel. Arguments for and against proposed standardization. The chief arguments against analysis purchase are that care and selection of raw materials, melting, hammering, reheating, rolling, inspection, etc., do not necessarily affect the analysis, but do affect the quality of the finished product. Skill and honor are necessary in making a good product. ROY H. DAVIS, *Iron Age*, 5-25-22, 3500 w. APS.

Purchase Specifications of Steel. Necessity for exact specifications in export trade because of varying significance of similar terms in different countries. Differences in standard threading. Specifications for bolts, nuts, rivets, wire and nails. Standard packings. Special finishes. Tables of comparative sizes of metric and inch threads. Metric and inch and gage sizes of wire, etc. JOSÉ MARIA GARMENDIA, *Export*, 5-22, 5000 w. APS.

Selective Case-Carburizing. Electrolytically deposited plate of copper furnishes most satisfactory metallic coating to produce localized case-carburizing. Non-metallic coating consisting of definite mixtures of sodium silicate with either finely ground asbestos or alumina furnishes good protection from carburizing conditions. It is easily painted on metal and may be removed by immersion in molten sodium hydroxide or by quenching in water. Colchlore in molten state is also useful in loosening these coatings. It is not felt that these coatings have universal application but it is believed that there may be many times when their use may not only be possible but also profitable in heat-treating shops. The coatings mentioned are not as efficient in preventing decarburization as they are in preventing carburization. W. P. WOOD and O. W. McMULLAN, *Chem. Met. Eng.*, 6-7-22, 2500 w. CJW.

LEATHER

Large Leather Stocks on Hand

ACCORDING to a recent estimate based on United States census figures, there is enough leather on hand to make 100,000,000 pairs of shoes. This supply is believed to be sufficient to permit tanneries to close down for the summer without seriously disturbing the shoe business. Census figures show that on March 31, 1922, there were 8,600,000 dozen pairs of cut soles, 11,600,000 backs, bends and sides of sole leather, 23,800,000 goat and kid skins, 8,600,000 calf and kid skins, 8,100,000 sides of upper leather made from cow hides, which makes a total of 250,000 feet of upper leather on hand. In addition there is also a quantity of horse-hide leather splits, cabretta, sheep, deer and elk leather. Altogether, they easily total to more than 300,000,000 feet of leather.

However, *American Shoemaking* points out that the census of leather stocks is a recent innovation, and that there is no means for making an accurate comparison of present accumulations with those of former periods. Never before in the history of the trade has demand been so whimsical—taking certain favored kinds of leather as fast as they could be produced, sometimes calling for more than the raw material made it possible to produce, and yet leaving enormous stocks of good leather of other kinds with no bidders for them. If a two months' shut-down were to take place now, every shoe manufacturer would have to exercise his ingenuity in making the best of what he could get and the retail stores would have to make their standards of quality more elastic.

Care of Leather. Suggestions for judicious selection of articles made from leather. Discusses selection and care of shoes, such as drying, oiling and greasing, waterproofing and polishing, harness, driving belts, book-binding leather and miscellaneous leather goods. F. P. VEITCH, H. P. HOLMAN and R. W. FREY, *Farmers' Bulletin*, No. 1183 (1922), 22 pp. CJW.

whip cord weaves, moleskin, alligator, pebble, straight grain, etc., finishing coats, drying and deodorizing. Uses for artificial leather are also given. *New West Trade*, 6-3-22, 2000 w. WRB.

Romance of Leather and Its Importance to Mankind. Part two. Continuing discussion of antiquity of leather using and asserting that its first use antedates written history. Cites instance of leather chair now in Cairo which had been buried 33 centuries and is still in prime condition. In early Egypt leather cutters formed a distinct sort of guild, and produced some very artistic work. They were of the third caste of society, next below the military, huntsmen and agriculturists. Thin leather in long rolls often used for writing—leather had a wide range of uses. Art of

tanning and dyeing well developed in ancient Egypt; lime was used for de-hairing. Illustrated. *Shoe Repair Service*, 6-22, 2000 w. WRB.

New Shoe with Moulded Insole. Description of a method to mould shoes to fit the feet, and in a manner permitting volume production. The principal feature of the shoe is that upper part or surface of sole, on which foot rests, is moulded to fit foot and resembles impression left by bare foot in pliable, moist sand at the seashore. The sole contains permanently moulded hollows or depressions into which projecting curvatures of foot rest, and rising curved surfaces that fit up under the several raised parts of foot. *Shoe Retailer*, 6-33-22, 2000 w. WRB.

Story of Artificial Leather. Description of materials and methods used in producing artificial leather. Cotton fabrics form actual foundation for building, and gun cotton is one of the principal ingredients of solution smeared over the cloth to form the imitation fabric. Article describes methods and equipment for washing and tentering, dyeing and bleaching, napping, special finishes, like

(Louisville Courier-Journal)
"His bum steer."

(Indianapolis News)
"One way out of it."

Market for Copper Reviving

INTENSIVE advertising, coupled with real merit, has been responsible for winning back the markets for brass and copper. The fact that their place was taken during the war by cheap substitutes and that huge stocks were piled up at the close of the war created a serious problem for producers. However, they were aided in their effort to win back customers by the rapid deflation in selling prices.

In view of the building boom and the revival in other trades, it is believed that demand for copper and brass will steadily increase. Because of copper's great malleability it is extensively used for both interior and exterior construction

work. It is estimated that 27 tons of copper wire and 90 tons of brass were used in the Woolworth building alone.

The value of copper as a rust-resistant also adds to the variety of its uses. Not less than 100 different automobile parts are made of copper and its alloys.

The stability of brass prices is indicated by the fact that although house furnishings and building materials went up to nearly two and a half times their former prices, and are now almost twice as high as they were before the war, brass is today selling at 15¼ cents, only one quarter of a cent more than the price at which it was sold in 1913.

Stellite. Stellite is alloy of cobalt chromium and other semi-rare metals. Does not oxidize deeply even at high heat, becoming covered with film of oxide, finally turning deep blue-black. Best results in welding is with use of oxy-acetylene torch; taking bars as made from scrap pieces of stellite, using silicate of soda as flux and making shape or form of tool desired. H. A. STEWART, *J. Am. Welding Soc.*, 4-22, 800 w. CJW.

Manganese Bronze in Engineering Work. Physical and chemical properties of manganese bronzes. Uses in engineering work, valves, trunnions, propellers, bushings, etc. Castings of 12 tons. Details of melting furnaces and foundry work. *Iron Age*, 6-1-22, 1500 w. APS.

Chromel Castings, Bars, Wire and Ribbons. Chromel is nickel-chromium alloy with high chromium content. Used for high temperature work in pyrometers, furnace resistances etc. Description of casting ingots, hot rolling, drawing in bull plates, and diamond die drawing, six figures. E. F. LAKE, *Brass World*, 5-22, 2000 w. (To be con't'd.) APS.

Marketing Silver Bullion. Importance of silver as a money metal, especially in Asia. Magnitude of the trade. The uses of silver. Annual production figures. Methods of trade, assaying, storage, insurance, etc. The establishment of prices at the various centers. Table of prices since 1910. PARKER D. HANDY, *Eng. & Min. Jour-Press*, 5-6-22, 2500 w. APS.

Copper Smelting in Central Africa. Ore dug out with hoes and hatchets, carried to copper smelter with his "medicine"; he spread out layer of charcoal 1.5 ft. in diameter, and placed on this successive layers of copper ore and charcoal, the whole being walled with clay 1.5 in. thick. When 3 ft. high, top sealed, and flame accelerated by bellows. Copper slag was collected and remelted. S. H. BALL, *Eng.-Min. J.-Press*, 4-22-22, 750 w. CJW.

Zinc-dust Fires. Fires in zinc-dust have sometimes given particular trouble owing to their resistance to extinguishers and liability of explosions. Foamite extinguished fire most quietly and effectively. Three 2.5 gallon foam extinguishers smothered fire from 300 lbs. zinc dust, but danger of rekindling passed on only after elapse of several hours, due to retention of heat in metal by non-conducting foam blanket. Although some fire-extinguishing materials may be injurious or may be decomposed in fires to produce toxic gases or vapors, no especial poisonous gases or fumes are evolved from burning zinc itself or from action of extinguisher material on zinc. S. H. KATZ and J. J. BLOOMFIELD, *Textile Colorist*, 6-22, 2000 w. CJW.

Welding Monel Metal. Must be de-oxidized in producing satisfactory arc-welds. These agents best employed in form of alloys, ground to 50-100 mesh and applied to welding rods of bare Monel metal as thin coating. May vary within moderately wide limits, but should introduce 0.05% to 0.50% magnesium, 0.20% to 1.0% silicon, and at least 0.20% manganese, an excess of which is not harmful. May also use nickel-magnesium, nickel-copper-mag-

nesium, or nickel-magnesium-silicon alloy. Aside from use of special de-oxidizer, arc-welding of monel metal is not essentially different from that with steel. P. D. MERCIA and J. G. SCHOENER, 5-22, 1500 w. CJW.

Arc-Welding Structural Steel. Tests made to determine reliability of welded joints and limiting conditions of various types of joints. Welding costs are less than riveting costs. Welded joint is fully as dependable as other joints. Cost data. E. S. HUMPHRYS, JR., *Iron Age*, 5-25-22, 7 Figs., 400 w. APS.

Standardized Costs for Sheet Metal Workers. Chapter 16. Proper application of shop overhead. Favors direct labor method of applying burden. Where much power machinery is used machine rate method of applying burden is advisable. Administrative and selling expense. ALFRED BARUCH, *Sheet Metal Worker*, 5-12-22, 3200 w. APS.

LUMBER-WOOD PRODUCTS

Demand for Hardwood Increasing

A STEADY and encouraging growth is noticeable in the demand for hardwood, and although at present this demand is being taken care of by reserve stocks, it is expected that because of very limited production the market will soon reflect the scarcity of stock. According to the *American Lumberman*, the flooring and interior trim manufacturers are the leading buyers. The automobile industry is also buying all the lumber it can find suitable to its needs, and agricultural implement manufacturers are transacting a considerable volume of business. If the expectations in regard to successful harvests are fulfilled, heavy demands are certain to be made this fall upon the retail lumber dealer for boxes, crates and packing lumber, and upon the agricultural imple-

ment and wagon manufacturer for new equipment requiring hardwood in its construction, as well as upon the suppliers of the farmer's numerous other wants.

Although there has been a decrease in buying by the furniture interests, this is said to be strictly seasonal. The furniture makers are unanimous in predicting a heavy business in furniture this fall, and a number of factories are planning to operate to capacity. All other domestic hardwood consumers are represented on the market, with a big aggregate of requirements. Even surpluses of the lower grades of hardwood have been materially reduced by the box and packing-crate interests, which have been active in the hardwood market recently.

Forest Products Industries of South. South's annual lumber cut is 11 billion feet and its products are valued at 310 millions dollars, giving employment to 250,000 men. Eighty-five per cent of remaining virgin yellow pine will be cut in 5 years or less and in 20 years all mills except 12 will have been reduced to only 3% of 1919 output. Climatic and labor conditions of region are such that timber can be grown cheaper than in any other part of country. Reforestation imperative. Research needed to solve certain problems which prevent or retard economic success of certain possible by-products of lumber industry. Discussion of rosin and turpentine industry from gum and chips and of the wood chemical industry. Another field is pulp and paper and ethyl alcohol from wood by fermentation. Allied interest is timber preservation. C. P. WINSLOW, *Chemical Age*, 4-22; *J. Ind. Eng. Chem.*, 5-22, 2500 w. CJW.

Commercial Woods of Pacific Coast. Total of 1707 billion feet of timber in Pacific Coast States available for lumber manufacture. Includes Douglas fir, Sitka spruce, Western red cedar, redwood, Idaho white pine, California white and sugar pine, incense cedar and Montana larch. Tables show annual production of each species, estimated stands, uses, properties and physical characteristics. C. W. GOULD, *Timberman*, 4-22, 3000 w. HHH.

Pacific Hemlock. Use of Pacific hemlock increasing. Wood is moderately strong, of fine, even grain, light in weight and color, odorless when dry. Soft enough to machine easily, yet hard and firm enough to wear well and take

good polish. Usually considered free from pitch or resin, since resin cells are few and scattered and do not affect uses of wood. Green Pacific hemlock contains relatively large amount of moisture, amounting to from 40% to 60% of its oven dry weight. Seasoning of great importance in reducing weight of lumber products before shipment. Chief uses of hemlock are in light construction work, flooring, car material, sheathing, boxes and crates, caskets, kitchen furniture and in substructure of veneer furniture. *Timberman*, 4-22, 2500 w. HHH.

Practice of Forestry. Requirements for keeping Southern pine lands productive are: (1) That 4 seed trees of longleaf pine or 2 seed trees of any other kind of pine be left standing on each acre of land cut over, or an equivalent of 40 and 20 trees on each acre. (2) That all tops and slash left in logging be removed to distance of 20 ft. from seed trees, unless twice prescribed number of seed trees be left per acre; slash to be burned first winter or protected by patrol and fire lines for 5 yrs. (3) Cut-over lands when reseeded to be protected from fires at all seasons for first 3 yrs. in case of longleaf pine, 10 yrs. in case of other pines, after which less careful protection is sufficient. R. D. FORBES, *Lumber Trade Jour.*, 4-2-22, 1200 w.

Uses of Basswood. Basswood one of most widely used woods for reason that, with exception of willow and buckeye, it is lightest, softest, weakest of hardwoods; neither stiff nor tough, of even grain, white color, extremely easy to work with. Most important factory uses

of basswood include: boxes and crates, millwork, woodwork and novelties, furniture and fixtures, trunks and valises, picture frames and molding, excelsior, musical instruments, toys, agricultural implements, vehicles, matches, refrigerators, car construction, laundry appliances, tobacco boxes. Also used for sounding-boards for pianos and organs, and in manufacture of veneers and plywood. *Lumber and Veneer Consumer* 3000 w. HHH.

What and Why a Cord? Critical comments on present systems of buying wood by old cord measure. Rot and bark important factors. Suggestion made to buy on weight basis, but this offers certain difficulties. Questionnaire has been circulated among mills to determine general method of wood measurement. B. T. MCBAIN, *Paper Trade J.*, 5-25-22, 1000 w. CJW.

Methods in Rubbing and Polishing. Three classifications of varnish—short oil, medium and long oil, depending upon whether they contain relatively large or small amount of oil. Varnish short in oil will dry much faster and rub easier than one long in oil. First step is to secure smooth surface by rubbing down with block of rubbing felt and medium coarse pumice stone and water. Rubbing with fine pumice follows, using paraffin oil instead of water. Obtaining good polish dependent on quality of polishing liquid employed. Following formula will produce durable polish with minimum amount of labor. Paraffin oil, 1 gal.; turpentine, 1 gal.; oil of cedar, 20 oz.; oil of citronella, 12 oz. Most difficult of polishing operations is known as "spiriting off." Speed and correct amount of alcohol used on polishing cloth the vital factors in determining perfection of final results. WALTER K. SCHMIDT, *Furniture Manufacturer and Artisan*, 4-22, 2000 w. HHH.

How to assure care-free valve service

IN SELECTING valve specialties "give Experience a voice." Your own experience will tell you that however good a device may appear, the only index to its practical worth is the gruelling test of time.

In gauging the value of Davis Valve Specialties you need not rely entirely on your own experience. Their ability to give care-free valve service at minimum cost has been written on the pages of the world's power plant log since 1875.

Davis time-tried features and authoritative design are found in the specialties listed below:

DAVIS VALVE STEAM SAVERS SINCE 1875 SPECIALTIES

USERS know. They will tell you that the longer you use Davis Equipment, the less it costs.

The strongest argument a Davis salesman can offer is the opinion of Davis users.

For however varied plant conditions the statement is always the same; when you put in Davis equipment you can forget it, but it will never forget you—or your coal bill.

Write for description of these time-proved specialties.

- Balanced Valve
- Water Control Valve
- Exhaust Relief Valve
- Water Relief Valve
- Stop and Check Valve
- Steam Trap
- Pump Governor
- Emergency Stop Valve
- Flow Regulator
- Non-Return Valve
- Fluid Lever Controller

The Davis Regulator—the regulator that has no springs to fail or diaphragms to cause trouble and shorten its life. Utilizing the positive principle of the simple balanced scale, it maintains a constant reduced steam pressure regardless of fluctuations in the higher pressure. Sizes $\frac{1}{2}$ to 14 inches. Illustrated above.

The Davis Back Pressure Valve, operating noiselessly and never sticking or binding, maintains a positive back pressure for heating, drying, cooking and other purposes. Sizes 2 to 30 inches.

The Davis Float Valve has a single seat with a renewable composition disc which makes it close tight and prevents leakage. It keeps the water in a tank or reservoir at a constant level. Sizes $\frac{1}{2}$ to 14 inches.

Write for details of these and the other valve specialties, listed opposite, to the G. M. Davis Regulator Co., 409 Milwaukee Ave., Chicago.

Replacing Skilled Labor with Machines

THE scarcity of skilled labor now becoming apparent is expected to result in an increased demand for machinery and machine tools. As the wages paid to skilled workmen advance, a greater effort is certain to be made to cut down costs and speed up production by the use of labor-saving machinery. In supplying the need for industrial equipment of all kinds, the machine industry is offered an opportunity for development along original lines. In many instances an effort will be made to secure greater production with the same number of machines, thereby creating a demand for a high-

grade product instead of the mere jobbing-shop type.

The *American Machine and Tool Record* points out that if the monthly barometer of figures available were giving the flow of orders by units or number of machines sold, instead of by a percentage of dollar values based on orders received during the first quarter of 1922, there would be evident a decided improvement in the machine-tool business over six or nine months ago. Prices are lower and therefore the percentage of orders based on dollar values is misleading and does not show the increasing activity.

Tool Design Standards. This article follows along the lines of, although entirely separate and distinct from, an earlier article on the same general topic. This one takes up the development of standard instruction sheets for the use of tool designer. As the author points out, much time is spent by tool designers in looking up dimensions on tools already made, also much time is wasted in designing similar details again and again. And in other ways, the lack of a uniform method of procedure wastes a great deal of valuable time. This author's plan is to standardize the method of procedure and instruction sheets to tool designers, so no work previously done will be done over, and no ground once covered will ever be retraced by someone else. H. P. LOSELY, *Machinery*, 5-22, 2750 w. MAH.

Production Work in a Contract Shop. Second of a series of articles describing work done by the Taft-Pierce Mfg. Co., Woonsocket, R. I. This article describes the unusual methods used in machining and testing an aluminum automobile fan for the Wills Sainte Claire motor. The bore of the hub includes a number of micrometer fits, while the fans must be in correct static and running balance. The shaft is described as well. *Machinery*, 5-22, 2800 w. MAH.

Careful Tool Set-Up Assures Better Production. Many and great possibilities in use of automatic machines, both single spindle and multiple, which are maximum production tools, and should be kept in such condition as to permit working at maximum rates all the time. All setting should be properly made in advance, effective feeding mechanism must be available to cut unproductive time, plenty of room must be provided for operator and extra stock, gears must be kept quiet and well lubricated, belts must be in good shape, good planning and sufficient forethought are necessary. Other pointers are given. DONALD A. HAMPSON, *Can. Machinery*, 5-4-22, 4500 w. MAH.

Machine Molding Thin Cylinder Castings. Textile machinery, thin cylinder with five re-entrant ribs. Difficult machine casting problem. Details of solution of problem. *Iron Age*, 6-1-22, 5 photographs, 2000 w. APS.

Soldering Fluxes for Machine Construction. Author looks upon welding, soldering, brazing and similar processes, in this case, as auxiliary tools for keeping the machine shop running all the time. He tells how to prevent oxide or rust, how to clear it away in a welding or soldering case, how to prepare the various fluxes, how to use them, how to unite dissimilar metals, and gives other pointers. W. B. STANDFORD, *Can. Machinery*, 5-4-22, 1900 w. MAH.

Bits. Following recommendations are made: Provide adequate containers for carrying bits and establish proper system of transportation and recording. Equip blacksmith shops with apparatus to resharpen bits to these specifications, quickly and at low cost and thus obtain advantages of properly shaped and absolutely uniform bits. Purchase proper steel for cutter bits and see that bits are intelligently and carefully heated and tempered for particular conditions prevailing in each mine. Lay special emphasis on importance of exercising care to avoid burning of steel. C. B. OFFICER, *Coal Age*, 5-18-22, 2000 w. CJW.

Pipe-Threading Tools and Their Manufacture. Modern type of pipe-threading die-stock is adjustable, so that several different sizes can be cut. Usually the number is four; medium size would cut 1-, 1¼-, 1½- and 2-inch threads. Methods used in making Beaver die-stocks and chasers. Illustrations include special turret lathes, special multiple-spindle drills, special broaching equipment, special duplex millers, etc. FRED R. DANIELS, *Machinery*, 5-22, 3600 w. MAH.

Comparator for Checking Precision Gage-Blocks. Pratt & Whitney use an interferometer or millionth comparator as an additional safeguard against mechanical errors in the manufacture of precision test blocks. This unusually delicate and accurate machine is used following the optical tests. The article describes the apparatus in detail, also the methods of using it, and the results obtained. FRANKLIN D. JONES, *Machinery*, 5-22, 4100 w. MAH.

Characteristics of the Different Forms of Gears. This is another part in a long series on this subject. The present article deals with the classification of gears, the continuity of tooth action, advantages of the herringbone action, molding generating process, etc. CHESTER B. HAMILTON, *Can. Machinery*, 4-30-22, 3350 w. MAH.

Gears Classified by Shaft Arrangement. Continuation of series of articles on gears in all phases. This article takes up their classification, particularly those whose axes are in different planes but not necessarily parallel. This includes worm wheels, in the helical, spiral and skew types. Author describes each, and tells how the tooth is generated or cut. He goes into their relative efficiencies somewhat, and reasons for the use of one in preference to the others. CHESTER B. HAMILTON, *Can. Machinery*, 5-4-22, 3200 w. MAH.

Advantage of Roller Bearings. Power consumed by spinning frame is considerable. Until recently comparatively little effort spent in improving bearings on cylinder shaft which delivers power to drive spindles and other parts of machine. Recent tests show power saving of more than one-half horse-power per frame, with exceptional durability and oil saving. C. W. NUGENT, JR., *Textiles*, 5-22, 1000 w. MBB.

Inspection of Mill Reduction Units. Niles-Bement-Pond methods outlined. Inspecting correctness of tooth shape and spacing; measurement of eccentricity, determining helix angle, checking shaft alignment, etc.; eight figures. R. H. RAUSCH, *Iron Age*, 5-25-22, 2000 w. APS.

A-B-C of Sheet Metal Working Machinery Application. Methods of double seaming by hand and machine with description of several types of double seaming machines suitable for various types of work. L. BROEMEL, *Sheet Metal Worker*, 5-12-22, figures, 1500 w. APS.

Why Bush Terminal Operates 51 Stuebing Lift Trucks

One man rolls a Stuebing Lift Truck under a loaded platform, lifts it with an easy pull on the steering lever, quickly moves it to any location and safely lowers it to the floor.

Mr. Irving T. Bush, manager of the great Bush Terminal in Brooklyn, says: "We have experimented with a number of trucks and have found the Stuebing Lift Truck System the cheapest and most efficient for our service."

Coming from a man skilled in transportation methods, and one to whom the cost of handling goods is a vital factor in determining profits, such an endorsement of the Stuebing System is especially significant.

Stuebing Lift Trucks will save money in your factory or

warehouse, too. These trucks eliminate the many repiling operations needed with ordinary platform trucks. They speed up the movement of case and sack goods, flat stock, heavy machinery and parts in process. They conserve floor space, operate easily in close quarters, and last for years.

There is a type of Stuebing Truck to suit every interior hauling need and a Stuebing engineer near you who will gladly talk over your hauling conditions with you. Get in touch with us today!

Stuebing Steel-Bound Platforms match the Stuebing Lift Truck in strength of build and adaptability of service. They won't wear down or wobble.

The Stuebing Truck Company, Cincinnati, Ohio

Stuebing
LIFT TRUCK SYSTEMS

PAPER

Paper Industry Returning to Normal

ACCORDING to the official organ of the American Paper and Pulp Association, October or later September will probably see the paper industry back to its normal position, which it can be expected to maintain through the next winter and spring, at least. Paper production and shipments for March were the largest since October, 1920. Although production is now equal to normal consumption, business is retarded because of the amount of over-capacity in the paper industry. For the next few years this will, no doubt, be the chief source of difficulty. It is believed, however, that if new machines are not added to the already over-equipped

industry that the line of normal growth of consumption will steadily advance to meet the country's capacity.

According to figures prepared by the Department of Commerce, exports were higher during March than during any month of 1921. But they are much lower, in proportion to production, than was the case in 1914. Since then the war exports have fallen off rapidly. In the case of newsprint, wrapping and book, three of the most important grades, the export percentage increased from 2.1% in 1914 to 7.5% in 1919, but dropped in 1920 to 3.6%, and in 1921 went below the 1914 figure, dropping to 1.9%.

Bamboo for Paper. Philippine Islands contain about 5,000 acres of bamboo, each of which should produce about 40 tons of pulp. This acreage capable of supplying 20-ton mill for 3 years without counting on growth of bamboo during this period. Working on 3-year rotation period would supply mill indefinitely. Quotations are given on use of soda and sulphite processes. *Paper Trade J.*, 5-18-22, 1000 w. CJW.

Bleached Groundwood. In order to secure continual production of high-grade bleached groundwood pulp there must be regulation within close limits of moisture content of pulp on wet machine or in bleaching engine by suitable means, as keeping wet machine felts clean, pressure properly adjusted and by measuring both water added to engine in inches and moisture content of pulp furnished. Use of only good, sound white spruce, balsam or poplar, thoroughly barked. Grinding conditions carefully specified and adhered to. Standardization and close regulation of all features of work pertaining to bleach itself, such as solution of definite and constant strength, temperature during application of solution kept constant at 40-60° C. as limits. If bleached on wet machine, frequent testing of bleached pulp for acid residues, indicating that bleach should be cut down, keeping all iron and metal work well painted with good acid-proof paint wherever it might be attacked by solution. Generally close supervision of steps of process, bearing in mind that it requires same degree of attention as does bleaching of any fiber. A. O. BRAGG, *Paper*, 4-26-22, 3000 w. CJW.

Testing Sulfite Pulps. Chlorine consumption method is proposed as method of determining approximate amount of lignin in pulp. Test must be performed at definite alkalinity of reaction liquid and at same temperature. Some relation between lignin content and chlorine consumption number and between these and bleaching capacity of pulps. R. SIEBER, *Pulp Paper Mag.*, 5-25-22, 1500 w. CJW.

Centrifugals in Soda Process. Desirous to remove black liquor from pulp as soon as possible to decrease bleach consumption and with as little dilution as possible to economize on recovery. Test with 10-in. Elmore continuous centrifuge showed that above 1950 rmp moisture

content of pulp was fairly constant at 57%, but baling of pulp was objectionable feature. Might be eliminated on larger machine. Washing tests on small machine were not satisfactory, but further experiments would be interesting and might be profitable to one contemplating construction of new mill. J. R. KESSLER and G. N. COLLINS, *Paper Trade J.*, 6-1-22, 800 w. CJW.

Yield and Strength of Soda Pulp. System which will prevent oxidation either by use of deoxidizing solution or by circulating system that will cover or submerge and penetrate all parts of mass alike and avoid as far as possible high temperatures will surely enlarge yield and improve quality of product. No system as effective as positive pump, so arranged that liquid may be circulated in either direction. M. L. GRIFFIN, *Paper Trade J.*, 4-13-22, *Paper Mill*, 4-15-22, 750 w. CJW.

Specifications for Limestone and Lime for Sulfite Pulp. Definitions of limestone and quicklime, composition of each, method of sampling and testing as submitted by the Committee on Sulfite Pulp (Revised Mar. 15, 1922). *Paper Trade J.*, 4-13-22, 1200 w. CJW.

Cleaning Pipes of Wood Pulp Deposits. Ground wood pulp (1 to 200 water) is transported 6000 feet with 33-foot fall through two 8-inch and one 12-inch pipe. Pipe is wood stave, wire bound. Pipe gradually fouled, reducing carrying capacity, and was found coated with slime. By an ingenious method of taking out a section of pipe and inserting a scraper which would be forced along by the water pressure the pipe was cleared rapidly. Three men working one 8-hour shift cleared 3000 feet of pipe in two sections. HOWARD L. ROPES, *Paper Mill*, 5-6-22, 1500 w. APS.

Silicate of Soda. Discussion of various forms. Silicate will produce joint much stronger than paper, and this joint will resist temperatures which would destroy paper and endures for time much greater than paper box is required to serve. Therefore strongest link in structure known as corrugated paper. Spreading capacity of silicate has improved with result that much less need be used. Best silicate is cheapest, because loss in waste board and labor greatly exceeds total cost of silicate. J. G. VAIL, *Fibre Container*, 5-22, 1000 w. CJW.

Manufacture of Waterproof Paper or Board. Depends upon introduction of asphalt simultaneously with formation of sheet. Asphalt is emulsified in such way that it forms non-adhesive emulsion. Highly colloidal clay used as emulsifying agent. Emulsion handled with pumps and may be introduced into beater or at machine. More convenient to handle emulsion at machine by introducing it into suction side of fan pumps which withdraws water from inside of cylinder molds to return to screens with raw stock on its way to vats. Asphalt acts as loading material without retarding drying and tonnage is substantially increased in proportion in which it is added. L. KIRSCHBRAUN, *Paper Trade Jour.*, 5-11-22, 1500 w. CJW.

Felts. Tentative sizes suggested: variations of only 2 ft. in length in even figures from 24 to 50 ft., then 54 and 56 and from there on, in 4-ft. lengths. Variations in width be confined to 4-in. at least 2-in. jumps. Two standard designs of bottom board felts, one for board where fineness of finish is necessary and another where greatest strength, openness and long life are prime requisites. In corrugated, shathing, roofing, groundwood pulp, and some others, single design should be sufficient. *Paper Trade J.*, 5-25-22, 750 w. CJW.

Accidents in Wood Room. Points out some corrections which will reduce accidents in wood room. Log haul-up should have cleated walk, wide enough for 2 men to pass. Slasher saws should have good, substantial wire screen between saw and operators. Cut-off saw should be protected in same manner. Walks should be provided along chain conveyors to reduce temptation to walk on them. Men running knife barkers should wear goggles. Attachments should be used to protect fingers. Up-right splitters cause accidents and care must be exercised. Caution must also be used in chip bin. D. B. DAVIES, *Paper Industry*, 4-22, 1500 w. CJW.

An Easy Way to Prove Rand Principles

Your problem may be entirely different from those of the Michigan State Telephone Company, and yet the same principles apply,—simplification through visualization.

All you need do is to send us a sample of your present record, tell us briefly how they are used, and our Systems Department will gladly submit details showing how your present records can be adapted to Rand Equipment and thereby give you the economy of plain sight records. This will be entirely without obligation on your part.

—and each year they get the benefit of an equal saving from the same source. That's putting business economy on a practical basis. Other economies realized add several thousand dollars more to the benefits received.

That's the story, briefly told, of what one institution,—the Michigan State Telephone Company—accomplished through the installation of

RAND Visible Index Systems

No, it wasn't an exceptional case,—merely typical of thousands of firms who have saved millions of dollars through the use of Rand Equipment.

And this saving is only one of the benefits. Various phases of business activity have been improved;—production increased, sales boosted, costs reduced, inventories improved, records simplified, and greater efficiency realized through every department.

Seeing Cheaper Than Searching

Today, as never before, profits come from economies,—from short-cuts which reduce overhead. Don't close your eyes to these conditions. It's cheaper to face the facts than to pay the price of hidden records.

Free Booklet for Executives

—the story of Rand Equipment told by busy executives who know from experience,—a story of thousands upon thousands of dollars saved through Rand Visible Records. Tell your secretary to write for it—Today!

Are Newspapers Profiteering?

THE high cost of newspaper space today is said to cut down profits on the goods advertised to such a degree that in many instances advertisers can no longer afford to use this means of presenting their message to the public. The increase in the rates of 282 leading daily newspapers is 79% over the rates in 1913, the increase in circulation 23%, and the increase in the rate per line per million circulation 46%. A number of advertisers have adopted the direct-by-mail method with notably successful results. Others have advertised their products by means of posters, and street-car cards and many have substituted magazines for newspapers when apportioning their advertising appropriations.

However, newspapers assert that they are not profiteering, that costs over which they have no control have forced them to raise their rates to the present level. According to the *Editor and Publisher* costs today are about 100% above those of 1913. Although paper is considerably cheaper than in 1920 and 1921 it is pointed out that newspapers did not set

their rates on the basis of 14 cent spot market paper. Many of them were paying less than that for the greater part of their supply—the rates were made largely when contract paper was seven cents a pound f. o. b. mill. Those rates would not have been sufficient had the panic period in the paper market continued, and most newspapers would have been forced to increase their charges still further or go out of business, according to this magazine. With paper at \$75 a ton it is still more expensive than in 1913 and there are no indications that it will approach closely to the 1913 level for several years, while spot paper shows signs even now of rising. This reason alone, it is said, would justify an advertising rate of 79% above the 1913 price, if there were no other factors. And in addition to the cost of paper, there are to be taken into consideration the expense incurred by the adding of editorial features, the wages of mechanical employees, and other operating costs that can only be reduced gradually, as the cost of living is reduced.

Evolution of Bookmaking. Last of two instalments, giving a short history of bookmaking in its earliest stages. This article deals with Caxton and contemporaries, pointing out the characteristics of early production, and describing the troubles of the early printers. JAMES MACLEHOSE, *Ben Franklin Monthly*, 6-22, 2500 w, illustrated. WRB.

Law of the Press. Third of a series, this instalment dealing mainly with the trial of criminal actions in newspapers. While practice is already restricted, author believes further bars should be raised in many States to prevent interference with courts. The author, a lawyer specializing in newspaper work,

develops many points in this phase of publishing and cites many instances in support of his contention. He also covers rights to news, subscription lists as capital assets, "paid" subscribers, and the ethics of publishing in general. ROME E. BROWN, *Editor and Publisher*, 6-17-22, 2500 w. WRB.

Apprentice Training in Europe. Foundation for good journeyman printer must be laid during apprenticeship, in the view of European printers, and it is on that fact that their system is built. Author describes instruction plants and methods in several European centers. MARTIN HEIR, *Inland Printer*, 6-22, 2500 w. WRB.

For Standard Paper Sizes. A review of the work of the United Typothetae of America in standardizing paper sizes and causing the abandonment of private watermarks. New catalog size of cover stock, 23x33, secured to fit standardized catalog, making for saving in paper stock. Recommendation for paper grade standardization. ALBERT W. FINLAY, *Ben Franklin Monthly*, 6-22, 1800 w. WRB.

True Freedom of People Dependent on Free Press, Says Churchill. British Secretary of State for colonies asserts in London speech that right to criticize must never be taken away. HERBERT C. RIDOUT, *Editor and Publisher*, 5-20-22, 500 w. MBB.

FIG. 1.—The Wrong Way.

FIG. 2.—The Wrong Way.

FIG. 3.—The Right Way.

THE INLAND PRINTER

How to cut leather for book-covers, loose-leaf devices and for other purposes in the bindery. In Fig. 1, where but four corners are cut in one pattern, the waste is one-ninth of all leather cut in this manner, while Fig. 2, showing six corners to the pattern, shows a waste of one-fifth. Using Fig. 1 as a pattern, but making it larger, holding, say, 16 corners, the percentage of waste remains the same. Do the same with Fig. 2, allowing 12 corners, the percentage of waste is materially lessened. Fig. 3 illustrates how to eliminate all waste. Although Fig. 1 is the wrong way to cut the leather corners, it shows the correct proportions. This is easily ascertained by drawing a perfect square on a piece of cardboard, dividing this into exact thirds on all sides and drawing four straight lines through the square, thus dividing the larger square into nine equal parts. Two straight lines drawn diagonally, with the center square blotted out, give a perfect corner. Dotted lines show division of square. The heavier lines show that a perfect corner is three times longer than it is wide. After marking out the pattern for whatever number is desired, it should be cut to shape, after which the hides of leather are cut to the pattern. All small pieces of scrap left over may be cut singly, thus utilizing practically every bit of the hide. The large pieces are piled straight in stacks of 50 or more, according to the thickness. Next, they are cut into strips on the paper cutter, and the full length of the pattern, after which they are sliced diagonally. At all times the marked-out pattern is brought into play, thus furnishing a guide for the actual cutting. Once the piles are cut into strips, a strong rubber band may be passed around each bunch of strips; this will hold them firmly for the diagonal cuts. As Fig. 3 shows, there is no waste at all when cut to such a pattern.—(Edwin R. Mason, in *Inland Printer*.)

YOU PAY FOR THIS

"It is discouraging to work here. I'm only a cog in the wheel. Impossible for a man to get ahead. Whatever I do, it is not appreciated. There must be a place where they appreciate effort. I may as well look around elsewhere and do something to better myself. I'm just going through motions here."

Similar mental attitude is common today. It costs money in lessened co-operation and reduced production.

How much of it is there in *your business*, what is it costing you, and are you doing anything adequate to improve it?

Prices of Cotton Goods Firm

IT is predicted that prices of cotton goods will not fall below their present level for some months to come. There is even a possibility of higher prices this fall, due to the fact that stocks in the hands of retailers are not large and that a certain amount of replenishment must take place. The textile strike has contributed to the firmness of the market, while the coal and railroad troubles are also important factors.

However, it must be remembered that our exports of cotton goods have fallen off considerably since last year and that as Europe recovers there may be heavy imports. Another en-

couraging factor is the recent cotton rate cut of 30% by Coast shipping lines, which it is hoped may have some effect in lowering the price of manufactured goods. The new rate for raw cotton from Galveston to New York will be 35 cents per 100 lbs. instead of 50 cents, and rates from other points will be lowered in proportion. Boston-Galveston prices will be changed from 76½ cents per 100 to 57 cents, while the charge from Galveston to the heart of the textile industry at New Bedford, Fall River and Providence will go from 88½ cents to 55 cents.

Testing Strength of Cotton Yarns. Explains purpose and nature of the strength test with details of carrying it out. Gives method of calculating for skein and single-strand tests. Suggestions for carrying out tests. *Cotton*, 5-22, 3000 w. APS.

Kier Boiling Cotton Goods. Most of available cotton is dark and difficult to bleach. To overcome shortage of high-grade cotton, progressive bleacher must continually seek to improve his methods. First steps toward such improvement consists in eliminating faulty practices, few of which are mentioned and substitute therefore the procedure which has proven correct both in theory and practice. F. J. WALL, *Textile Colorist*, 6-22, 1200 w. CJW.

Ribbons and Carbon Paper. Ribbon fabric made from long staple Sea Island or Egyptian cotton very closely woven. Ink applied to fabric by means of padding machines, using steel or soft rubber rolls. Inks are dry colors ground in oil, several days being required. Colors used are given. Carbon paper inks are essential mixtures of wax, color and oil. After mixing, remelted and applied hot to tissue in coating machine which regulates and equalizes an amount of ink applied. Then passes over rolls kept cold by cold water which suddenly chills and sets the ink on tissue. P. J. HASSETT, *Am. Dyestuff Reporter*, 6-5-22, 1000 w. CJW.

Stripping and Dyeing Shoddy. Colored rags treated with dilute oil of vitriol, squeezed and baked, which destroys linen and cotton threads and fragments. Then passed through willow and finally stripped. Brief description of bichromate of potash and oxalic acid process and also hydrosulphite stripping. Desirable that woolen garments should not be stripped. In redyeing garments that have been stripped are first thoroughly washed of stripping solution and preferably dyed in rotating machines. Choice of dyes restricted to "unions," which will always give best results provided sufficient time is allowed for dye to go on wool at higher temperature necessary for that fiber, and allowed to cover cotton in cooling bath. L. J. MATOS, *Cleaning and Dyeing World*, 5-22, 1500 w. CJW.

Reclaimed Fibers. Cotton and wool substitutes procured from remanufactured or reclaimed classes of fibers. Remanufactured fibers include shoddy, mungo,

noils and flocks. Shoddy originates from soft rags, tailors' clipping, blanket cuttings and kindred stock. Waste of knit goods also utilized in shoddy lots. Mungo is result of grinding into soft, fibrous condition, old rags, waste of knitting mills, clippings from clothing manufacturing, soiled rags, gummed rags and rags not suitable for making shoddy. Noils not all inferior fiber; are commonly short, curly and uniform. Flocks chiefly made from droppings from beneath shearing machinery. Flocks used in fulling mill where they are pounded into texture of woven fabric, increasing its weight and stability. *Southern Textile Bul.*, 5-28-22, 1800 w. HHH.

Woolen and Worsted Cloth Finishing. Methods employed in drying textile fabrics after scouring or washing off, should receive consideration from viewpoint of utility, economy and production. Wringers or squeezers frequently used for removal of moisture. Double squeezer effective for woolen goods, of heavy type, but for worsted fabrics single squeezer should be used. In dealing with worsted fabrics pressure needs to be reduced as compared with that permissible for woolens; should never be used on crossbred worsteds. Hydro extractors also employed for removal of moisture. *Textile American*, 5-22, 2000 w. HHH.

French Worsted Spinning. Each type spinning machine has own method of yarn winding. By applying same laws by means of different mechanical arrangements same result is reached in both cases. Mule winds intermittently each draw of yarn spun, spinning frames wind yarn as fast as spun, spinning and winding being continuous and simultaneous. LEON FAUX, *Textiles*, 5-22, 800 w. MBB.

Dyeing Worsted Piece Fabrics. Most important operation is in scouring. This requires use of good and practically odorless soap, sufficient volume of scour liquor and more or less close regulation of temperature and time. Thorough rinsing also necessary. Advantage to wash fine goods after carbonizing and before dyeing. Dyer should be informed of changes in manufacturer's cloth stock. Dyes should be brought into complete solution before adding to bath. Working suggestions for variety of shades given. L. J. MATOS, *Am. Dyestuff Reporter*, 5-22-22, 1200 w. CJW.

Homespun. Great variety of effects obtainable. Wools used in blending should be dyed with colors fast to milling and washing. Wool to be bleached should be well scoured and evenly wet out, immersed in bath of permanganate then in bisulphite and sulphuric acid. Dyestuffs recommended. Good grade of wool oil should be used to eliminate the harsh scouring. Palm or olive oil soap give good results. After washing, extract, dry, steam, shear fairly close on both sides with raising and laying-on brush both in use. G. E. TEMPLETON, *Am. Dyestuff Reporter*, 6-5-22, 750 w. CJW.

Naming and Numbering Yarn. Yarn in factory should be properly distinguished, both in color, counts and qualities. Best system is to have only one number for each color throughout all qualities and different count number for each quality. By having one number for each color, those who deal with yarn get to know color easily and so are less likely to make mistakes. By having different count for each quality danger of using saxony for cheviot or vice versa is reduced to minimum. If two or more qualities or makes of yarn are required in same counts, they are differentiated by fractions. In this way yarn is fully described by its number and its counts. Thus: 600, 28 cuts; 600, 28, ¼ cuts; 600, 28, ½ cuts indicate same color in three different qualities or makes. In all cases, spinner would understand fractions are for purposes of identification, integers only being counts. THOMAS WALSH, *Textile American*, 5-22, 1500 w. HHH.

Shady Piece Goods. Source of trouble rather hard to locate. Writer traces worsted piece through various processes, crabbing, steaming, fulling, washing, dyeing, and drying, and considers results which could occur in form of shadedness later, if particular process were not carried on in a manner to obtain proper results. L. N. PUTNAM, *Am. Dyestuff Reporter*, 5-8-22, 1200 w. CJW.

Cause of Nibs or Lousiness in Dyed Silks. Micrographic study of dots and nibs in dyed silks reveals that channeling is due to extremely thin fibrillae of sericin contained in the fibroin. Lousiness also caused by silk with low cohesion. This cohesion affected by quality of cocoons and district from which they come. Following conditions affect cohesion:

Labor Problems *Worth-while Books for Industrial Executives*

NO one can intelligently handle or discuss labor problems without a practical working knowledge of the fundamentals involved. Such knowledge is often beyond price, as many executives in the coal industry at this time are having forcibly brought to their attention. Below is a selected list of books, the product of experts in the labor field, which every executive should have in his library. These books are only a few of the many on labor that can be obtained promptly through THE INDUSTRIAL DIGEST, just as labor is only one of the hundreds of industrial subjects, covered by the Book Department of this magazine. Tell the Book Editor what you want.

THE SETTLEMENT OF WAGE DISPUTES, by *Herbert Feis.*

This book concerns the fundamental problems of wage disputes and principles of settlement. It discusses the principles of wages, wages and price movements, the standard wage, the living wage, the regulation of wage levels and a concept of industrial peace. Clients who wish a comprehensive discussion of these problems will be interested in this book. 289 pp. \$2.25, postpaid.

WORK, WEALTH AND WAGES, by *Joseph Husslein.*

Covers in popular form and very briefly twelve or thirteen subjects which are prominent in labor discussions, and it relates current discussion of these things to the Catholic Church. Catholic clients in particular will find this book interesting, and all who are interested in modern developments will find the book profitable. 159 pp. \$1.00 postpaid.

WHAT'S WHAT IN THE LABOR MOVEMENT, by *Waldo R. Browne.*

A comprehensive dictionary of labor terms. It deserves a place on the desk of every executive who wants to know the meaning of the terms commonly used in the daily papers and in the va-

rious magazines which touch upon labor and economic subjects. *Waldo R. Browne.* 578 pp. \$4.00, postpaid.

SPENDING THE FAMILY INCOME, by *E. A. Donham.*

This is a popular presentation of the whole budget proposition. It should be interesting to executives who are concerned with savings plans for employees. Contains a suggestive bibliography of literature on the budget question. 174 pp. 1921. \$1.75, postpaid.

THE INTERNATIONAL PROTECTION OF LABOR, by *Bontell E. Lowe.*

A short and careful review of international development. Discusses the action of all the international congresses and the various labor treaties and contains a bibliography of sources on international aspects of the labor situation. An excellent reference book. 439 pp. \$2.50, postpaid.

AMERICA VS. EUROPE IN INDUSTRY—A Comparison of Industrial Policies and Methods of Management, by *Dwight T. Farnham.*

Recounts the observations and experiences of a competent observer who has traveled widely among industrial plants in the

United States and in Europe. He compares the organization, administration and physical features of industry in the principal European countries with corresponding things in the United States. It is a readable book, attractively made up, and contains considerably valuable material. 492 pp. \$4.00, postpaid.

LABOR TURNOVER, LOYALTY AND OUTPUT, by *F. H. Colvin.*

How workmen in shops, factories, etc., may be induced to take an active interest in their work; the relation of employer and employee in shops. 152 pp. \$1.50, postpaid.

LABOR AND THE EMPLOYER, by *Samuel Gompers.*

A review and commentary on labor movements, aims and problems in the United States. 320 pp. \$3.50, postpaid.

THE FOUR-HOUR DAY IN COAL, by *Hugh Archbald.*

A study of the relation between the engineering of the organization of work and the discontent among workers in coal mines. 148 pp.; charts and tables. \$1.50, postpaid.

THE AMERICAN ERA, by *Harry Powers.*

Economic conditions of labor and labor classes in the United States. 309 pp. \$1.40, postpaid.

Book Department, INDUSTRIAL DIGEST

25 West 45th Street, New York City

temperature of water, speed of reeling, cross or croisure made during spinning, cleanness of water, mineral salts in water. Silk stored for long time in dry place will have low cohesion. Nibs are only defect made by worm; all other defects, such as raw knots, slugs, bad throws, corkscrews, large knots and loops are made during spinning operations. Dyeing operation must be so carried on as to develop these defects as little as possible. Boiling off must be done very carefully, skeins handled as little as possible. I. C. LEWIS, *Silk*, 5-22, 1200 w. HHH.

Construction of Weaves. Double cloths can be made with third set of threads which may lie loose between back and face or used to stitch face and back fabrics together. Double cloths can be weighted by third set of threads lying under regular set in either warp or filling. If double fabric, extra heavy, both stitching and stuffing threads can be inserted. Wraps with extra stitching or stuffing threads should be reeded to bring these in dent with regular threads on each side. *Textiles*, 5-22, 600 w. MBB.

90° F. using 20 gal. per 100 lbs. of wool. Let this saponify for 10 min. or so, then open sud box and let dirty emulsion away to drain. When machine is empty, add alkali as before, about 5 gals. per 100 lbs. of wool, run for 20 min. or so, and wash down. Warm water used at first and slowly, then stronger and colder. Directions also given for fancy worsteds scour and for "low-grade" scour. J. SCHOFIELD, *Am. Dyestuff Reporter*, 5-8-22, 2000 w. CJW.

Popular Textile Chemistry. This article covers chloride of lime and chlorine bleaching chemicals. JAMES A. BRANEGAN, *Cotton*, 4-22, 2800 w. To be continued. WRR.

Proper Use of Wood in Connection with Dyehouses and Bleacheries. In roof deck it is necessary to prevent penetration too far of moist air coming up from below. Thickness of roof deck must be such that temperature of sheeting will point out where moist air of room would yield a condensation. Exclusive of sheeting put on under surface of moisture-proof sheeting, roof deck

considerable trouble. Important to have sufficient sulphide of sodium and soda ash in dyeing with sulphur dyes, especially with light tints. This is necessary in order to hold first small additions of dye in solution and prevent any tendency for it to be precipitated on yarn. Dyes of poor solubility are very apt to cause streaky dyeing in beam dyeing machines. W. F. HASKELL, *Am. Dyestuff Reporter*, 5-8-22, 750 w. CJW.

Maintenance of Textile Machinery. Textile machinery is discussed from a maintenance and depreciation standpoint. The author points out the advantages of ball bearings as reducers of friction and thus of power needed to run, also of proper lubrication. He calls attention to the methods of automobile makers who specify that certain designated parts must be lubricated every 500 miles, others every 1000 miles, and so on, and suggests the quality of lubricant as well; he feels that a similar condition may work out in time within the textile and other machinery fields. Some common abuses are mentioned, and easy methods of correcting them. EDWIN H. MARELE, *Mechanical Eng.*, 5-22, 2800 w. MAH.

Review of wool consumption and imports, and cotton consumption and exports.—(*Textile World*.)

Knitting Double Fabrics. Circular machine joins two fabrics by stitching them at intervals. Machine has two sets of needles, cylinder and dial, two or more feeders, some supplying yarn to dial, others to cylinder needles. Sets work independently of each other, producing separate webs; additional yarn introduced, interlaces with loops of two webs, tying them together. *Textiles*, 5-22, 700 w. MBB.

Scouring and Milling. Three types of scouring: Solvent scouring, in which fats and oils are extracted from fiber by direct solvent action; saponification scouring, in which free fatty acids are converted into soaps; emulsification scouring, in which greasy dirt is removed mechanically by formation of frothy lather or emulsion. In saponification scouring, 3 stages: Run in soda ash solution of 5 to 6° Tw. at about

must not be made thinner. Outside temperature requires consideration. Permissible minimum temperature just under deck must be fixed. Prepared wood is perhaps cheapest material for use in top part of deck to prevent moisture insulator beneath from getting too cool. An inferior grade of lumber may be treated and made acceptable, creosoted wood of common variety all right, should be one inch thick; preservative may be applied on spot or wood bought ready treated. (Cont'd.) JOSEPH WOODMAN, *Textile Colorist*, 5-22, 2000 w. MBB.

Uneven Warp Dyeing. Caused by some mechanical failure or error of judgment in use of dyestuffs and chemicals or by simple carelessness. Dark places caused by interruption of progress of warp through dye-bath are apt to become scattered through large lot of yarn in processes subsequent to dyeing and cause

How America's Leading Men Safeguard Their Health

By Frank G. Soule

FRANK G. SOULE

HOW many times have you picked up your morning paper and read something like this:

"Mr. John Smith, the well-known merchant, was stricken last night in his

home with an acute attack of _____. He died before medical aid could reach him. Mr. Smith's sudden and untimely death will come as a profound shock and tragic surprise to the entire community as he *apparently had been in the best of health!*"

Mr. Smith's "sudden" and appalling death got into the papers because of his prominence. But for every Mr. Smith there are thousands of men and women stricken, and snatched away in the prime of life, people whose "sudden" deaths are not of enough importance as "news" to be recorded.

And Mr. Smith *apparently had been in the best of health!* But as a matter of fact his death was not "sudden." Like hundreds of men in your very community are doing today, *he had been dying for years without knowing it.* Had he taken the same precautions with his precious human machine that America's leading men now take with theirs, he might have been spared for many years of healthful, vigorous life.

For it is true that always, for months, even years, there are unmistakable indications in every person's system which shows definitely and conclusively exactly what is wrong. But the pity of it is that the diseases which cause these "sudden" deaths in the prime of life, diseases that often carry off little children, almost in the twinkling of an eye, are so insidious in their attack that there is no outward symptom of their presence until the victim has passed beyond all hope of recovery. In fact, an alarming feature of these diseases is that the very poisons in the blood which cause such "sudden death" often give a fictitious stimulation which gives the victim all the appearance of good health; rosy cheeks, bright eyes and unusual energy. Yet all the time the body may be slowly but surely breaking down under the vicious influence of these unseen poisons.

Because there are 600,000 deaths in the United States each year from preventable

diseases—because there are 3,000,000 people sick all the time, most of them needlessly so—because many of these insidious diseases stimulate a fancied feeling of good health and energy—because there are no outward signs which show that the system is slowly getting to the point where "sudden death" is likely: It is for these reasons that America's big men have demanded some kind of efficient protection against the lightning-like death that strikes everywhere, everyday.

Fortunately there is a way to know when this unseen and unfelt disintegration has started, and there are many simple ways of checking the progress of the diseases and restoring the patient to perfect health. Science can warn you of approaching danger, protect you and your loved ones from these diseases and add, perhaps from ten to twenty years to your normal life span.

It is by the use of these scientific measures that America's Leading Men: such men as Wm. Wrigley, Jr., Carl Laemmle, President of the Universal Film Company, George Ade, the Famous Humorist, Chick Evans, the Golfer, Paul A. Harris, the founder of the Rotary idea, Justice O. N. Carter of the Illinois Supreme Court and thousands of other men at the heads of their professions—brokers, lawyers, judges, doctors, preachers, manufacturers, builders, contractors, publishers, editors and writers—protect themselves against, and have ample warning to ward off the slow disintegration caused by sedentary living, lack of exercise and high pressure brain work. These men—every ninety days—without leaving their offices and without spending more than four minutes each year, obtain the most thorough and complete analysis of their physical condition ever made and receive a detailed report showing exactly what may be wrong. In addition they receive a sheet of helpful suggestions for correcting the trouble and warding off the disease that might otherwise strike death into their midst, deprive their businesses of their guidance, their friends of their association and their loved ones of their protection.

A few years ago, such a service as this—by virtue of its cost and inconvenience—was out of the reach of most men. Only moneyed men could afford to undergo, at the hands of specialists, an examination which showed the exact condition of their bodies. But now, thanks to the corps of trained Scientists and specialists maintained by the National Bureau of Analysis this service has been put within the reach of every man and every woman and made available for every child at a cost which is insignificant when compared with the value of human life.

Send for Free Book on Health

Remember that personal appearance and a feeling of well-being are not always an indication of good health. Instead, the

WILLIAM WRIGLEY, JR., president of the company which bears his name, is one of the hundreds of leading American business and professional men who safeguarded themselves against serious illness and "sudden" death.

very feeling of good health and energy which you have today may presage a breakdown, possibly a long illness—possibly "sudden" death.

Do not live in a fool's paradise of fancied good health. Accept the friendly warning of an unbiased and unprejudiced organization such as the National Bureau of Analysis and find out at once what is really happening to your body, unknown to you. Send at once for our brochure entitled, "Why People Die Too Young." It will not obligate you in any way. No solicitors will bother you. You will not be urged to subscribe to the Bureau's Service. But with this booklet in hand you will be better able to tell exactly whether you need such a life-saving service as the Bureau offers and exactly what it can do for you. Show the brochure to your physician if you like. Get his opinion. Then even if you do not subscribe, the knowledge gained from a reading of this valuable treatise will be of inestimable value to you. Simply fill in and mail this coupon today.

SUGAR CONFECTIONERY

Sugar Prices Will Not Rise

THE fact that a considerable surplus of sugar will be available for use in this country until the end of the year indicates that prices will remain at or near present levels, says *Fountain Profits*. This prediction is based on a survey recently conducted by the Federal Sugar Refining Company. According to itemized estimates of stocks, consumption and production, there will be 1,246,047 tons of sugar in excess of our needs in this country and in Cuba on Oct. 1 and on Jan. 1, 1923, there will be 1,396,947 tons of surplus sugar here and in Cuba. A total of 4,171,947 tons of refined sugar will be available before the new domestic crops come to market. The raw sugar aggregate is estimated to be 4,163,383 tons. Allowing 625,000 tons for exports from Cuba or the United States during the rest of the year, the balance available for

domestic requirements is 3,546,947 tons. Placing the consumption for the last quarter of the year at 950,000 tons, the carry-over on Jan. 1, 1923, should be, conservatively estimated, 1,396,947 tons.

It is estimated that Cuba's crop this year will amount to 3,580,571 tons. The yield of sugar is unusually high, many centrals reporting as high as 14% in some of their runs. Moreover, Europe's sugar industry is regaining its pre-war production. Preparations are now being made for the next crop, and it is expected that France will have more than its last crop of 300,000 tons and Germany will exceed its last output of 1,320,000 tons. English refiners are making vigorous efforts to reach their maximum capacity, and this competition is likely to affect American refined sugar.

Java Sugar Industry. Description of the industry and some of the chief factors which have made it a success. *Sugar*, 4-22. WRR.

Sugar-Beet Culture (continued). This number covers irrigation and alkali—elements of plant growth and effect of fertilizer, crop rotation. C. O. TOWNSEND, *Sugar*, 4-22, 6000 w. WRR.

Invert Sugar. Although it is commonly believed that sugar may be conserved by inverting it, it is shown that if sucrose is assigned sweetening value of 100, sweetening value of invert sugar is only 85. Since 100 units of sucrose become 105 units of invert sugar, net loss in sweetening power by inversion is about 11 units. Invert sugar may be of advantage in some places because it does not crystallize so easily as ordinary sugar sirups. Invert sugar sirup prepared practically devoid of flavor, provided less acid is employed. 0.013% by weight of C. P. hydrochloric acid (37%) based on weight of sugar and water taken is recommended. Boiling for 20 min. with this amount of acid will be sufficient to invert practically all of sucrose present. 0.021% of tartaric acid for 40 min. inverted 96% of sucrose. These sirups gave slightly harsh sensation which, however, was not produced by finished beverage. Invert sugar sirup prepared with invertase and concentrated was practically colorless, possessed only slight candy flavor and was remarkably smooth when taken in mouth. Superior to sirups prepared by acids. These make satisfactory bottled sodas. Those made by usual formulas do not make first-class lemon sodas, orange sodas, or other delicately flavored products. J. W. SALE and W. W. SKINNER, *J. Ind. Eng. Chem.*, 6-22, 4000 w. CJW.

Each acre of walnut trees in bearing will produce every year food approximating 2,500 pounds of beef.—*The North Woods*.

There are 261,553 women farmers in the United States.—*Tractor World*.

Sugar Substitutes. Lactose; maltose; glucose; levulose; derivatives of coal tar. Last prohibited in U. S.—*Confectioners Gazette*, 4-22 500 w. WRR.

Ice Cream Mixes Standardization. Gives practical methods, with tables, of making standard mixes. BENJAMIN MASUROVSKY, *Ice Cream Trade Jour.*, 4-22, 1800 w. WRR.

Food Flavors. General discussion of origin and preparation of aromatic substances, oleo-resins, essential oils, terpeneless essential oils, and emulsions,

purest form of milk obtainable. It will keep indefinitely, permits of constant supply of milk at all times, saves freight and express bills, allows uniform mix in manufacture of ice cream. Lack of milk solids, not fat, produces ice cream of large grain and has tendency to be icy. Over amount produces cream that, when hardened, breaks with cleavage of dry putty, while super-amount produces cream salty and soggy in consistency. N. C. HOAG, *Ice Cream Trade J.*, 5-22, 1200 w. CJW.

Carbonated Beverages. States that advertising appeal has not made proper impression—still considered as a luxury. *Soda Dispenser*, 3-22, 1100 w. WRR.

How and Why of Candy-Making. First of 12 articles, this instalment dealing with cream centers. Author tells of original centers and their disadvantages, development of the industry and its influences, chemical difference between cast and hand rolled centers, attempts to solve problem of fermentation, first use of invert sugar as the remedy, what happens inside centers after they are cast or rolled, machinery for forming hand rolls, how fondant should be used, methods of coating centers. MATTHEW BERMAN, *Candy Factory*, 7-22, 3000 w. WRB.

Sanitary Control of Ice Cream. Author reviews control efforts. Instances of early investigations showing that majority of plants were so constructed as to contribute to excessive bacteria in finished product. Since then general improvement has been noted. Milk products are chief causes of bacteria in ice cream, and gelatine may add materially to number present. Manufacturing, handling and selling equipment are other sources of contamination. Softening and then rehardening results in significant increase of bacteria. Temperature should be constant. PROF. JAMES O. JORDAN, *Ice Cream Trade J.*, 6-22, 3000 w. WRB.

Railroad Equipment Purchases Show Increase

THE marked improvement in business and the expectation of further expansion is reflected in the heavier movement in traffic and the increased activity on the part of railway equipment concerns.

According to the latest available reports, railway executives estimate that freight cars ordered in this country totaled approximately 80,000, or about three times the number purchased in the twelve months of 1921. It is expected that before the end of June approximately 95,000 new freight cars will have been ordered in the first half of the year, or at an annual rate of 190,000 cars. The following table, compiled by railroad statisticians, shows the freight car production for

the last 20 years and reflects the fluctuating demands of industry throughout that period:

	Domestic	Foreign	Total		Domestic	Foreign	Total

Self-Propelled Cars on Steam Railways. Largely a technical description of the motor car just purchased and put into

operation by the Greater Winnipeg Water District Commission, over its railway from St. Boniface, Man., to Shoal Lake, adjoining Lake of the Woods, a distance of 92 miles. The car is 42 ft. 6 in. overall, and weighs 13 tons. It is powered with a four-cylinder motor. Seating capacity totals 38, plus 8 in the baggage compartment on folding seats. In addition, article describes in similar detail storage battery car of the Canadian National Railways, which is being operated between Bathurst and Campbellton—63 miles. *Can. Railway & Marine World*, 5-22, 4000 w. MAH.

New Interlocking R. R. System. Large electro-pneumatic plant at Phillipsburg, N. J., uses new operating mechanisms and lead-covered cables. Detailed description of various parts of the installation is given. *F. W. BENDER, Railway Signal Eng.*, 5-22, 3500 w. IG.

Operation of an Electrified Terminal. Detailed description of the operation of the Broad Street Terminal of the Pennsylvania Railroad in Philadelphia. Comparison is made with steam operation. *L. E. LYNDE, Electric Traction*, 5-22, 2500 w. IG.

Handling Finished Product. Standard types of equipment listed below. Discussed in future articles. Class 1. Handling equipment for finished products in bulk or unpacked form: (a) Flat belt conveyors, (b) Troughed belt conveyors, (c) Bucket elevators—various types, (d) Screw conveyors, (e) Apron and pan conveyors, (f) Slat conveyors, (g) Scraper and flight conveyors, (h) Drag chain conveyors, (i) V-bucket and pivoted bucket elevator conveyors, (j) Cranes, hoists and monorails, (k) Storage-battery or gasoline-motor driven industrial trucks and tractors, (l) Lift trucks—hand or power propelled, (m) Compressed air conveyors, (n) Pumps—all types, (o) Industrial railways.

Class 2. Handling equipment for finished products in various kinds of containers, or on platforms or palettes: (a) Gravity roller conveyors, (b) Spiral chutes, (c) Straight slides, (d) Apron conveyors, (e) Slat conveyors, (f) Bar conveyors, (g) Chain conveyors, (h) Flat belt conveyors, (i) Inclined package or barrel elevators—bar, slat or apron type, (j) Vertical package elevators and lowerators, (k) Storage-battery or gasoline-motor driven industrial trucks and tractors, (l) Lift trucks—hand and power propelled, (m) Tearing machines—self-propelled and hand-propelled, (n) Cranes, hoists and monorails, (o) Industrial railways.

Class 3. Automatic machines which handle product in such operations as cutting, filling, wrapping and packing vary with every case and are impossible to name. They are generally the result of design growing out of special studies and experiments with particular product and process to which they are to be adapted. *G. L. MONTGOMERY, Chem. Met. Eng.*, 5-3-22, 2000 w. CJW.

Pneumatic Conveying System for Emptying Fibre Bins. Description of pneumatic conveying system using double fans, operating two-stage blowers, to handle steamy and matted stock. *JOHN L. ALDEN, Heating & Ventilating Mag.*, 5-22, 700 w. CS.

Muscle Shoals

(From page 1213)

men who own farms nearby, and thus put into effect another of his pet ideas. He would operate cheap self-propelled barges on the river—aquatic flivvers. He would build a new Detroit in the South. But, most of all, he would sell cheap fertilizers to the farmers of America, and enable them to grow four ears of corn where one ear grew before.

"I am afraid the idea of this development of Muscle Shoals is being thought of too much in terms of dollars and cents; of manufacturing and profits," said Mr. Ford.

"What I want is for the average man, the small farmer and the wage-earner, to visualize what it means to him. It is no money-making matter to me. I don't want any profit out of it; don't need any more money. It is a great boon to humanity I hope to leave behind me as evidence of my desire and effort to make things better for the people who have not had the fates smile kindly upon them; just the average folks who find things are pretty hard along the pathway of life.

"It means, first of all, that the farm man will benefit most directly. It will mean the saving in labor to him, an increase of production and therefore an increase of return to him.

"Nitrates for fertilizer are merely power arrested by these electrical processes and concentrated or fixed in the form of crystals.

"If the farmer can buy the power now going to waste down the channel of the Tennessee River, floating idly out to sea, put a few pounds of that power under his cotton or corn and realize more return on one acre than he now realizes from four, and obtain that power at one-fourth of what he now pays for nitrate, what has been done?

"He has been saved the labor on three acres of which he got comparatively no return. That same labor expended on four acres with the use of cheap nitrates will increase his productive power in the same ratio, consequently his earning power and his income and his prosperity. It means better homes, more advantages, better education, more comforts and easier life and more happiness.

"The manufacturing wealth of the country is vastly less than the agricultural wealth produced from the laboratory of nature and out of the soil each season. Each farmer is really a producing chemist, and Mr. Edison and I propose to furnish him with raw materials cheaply, conveniently and better.

"The farmer is a manufacturer also, the same as I am, only he is manufacturing the most basic and fundamental necessities of humankind. In spite of his production of the things without which would come famine, want, woe and misery, he has had less help and less before him by science or capital than almost any other class of people in the world.

"There is not a farm in this whole country that will not feel the benefit and the stimulus of this waste power being arrested and fixed in nitrate crystals, again to be transformed into vigorous plants and abundant fruit. It touches every farm in the United States.

"The widespread basic prosperity will give a firmer foundation for the rest of

our people. Say what you please, the farmer is the very ground beam of our national life, and, next to him in usefulness, the worker in other lines who exchanges his strength, skill or knowledge for daily bread.

"The surplus power after supplying the farmers with cheap fertilizer will accord employment for many thousands of people. It will turn many wheels now non-existent. It will create new wealth out of raw materials and effort and skill, and, I hope, with more equitable adjustment of rewards to those concerned than generally exists today.

"It will enable thousands of people to sell their raw materials. It will afford facilities to many additional hundreds to engage in more individual efforts at the production by making power more easy

to obtain and use in the small industries and will develop initiative and experiment in pioneering along manufacturing lines.

"It will enable the conservation of our coal resources and the proper utilization of this, our most amazing, potent gift from nature more heavily laden with useful so-called products than any other known substance. In the utilization of this coal as it should be used there will be many more factories and processes affording employment to a huge number of people.

"And all of that as a permanent thing, growing out of what is now a waste. Something not of value at all, but rather a colossal loss to the people every day because the people are not receiving the benefit from it."

What's Wrong With Coal?

(From page 1201)

"There is no independent family physician building up a practice by competing with other physicians. There are no local lawyers settling the community's difficulties over property rights, because the ordinary citizen has no property rights and can secure none.

"It is seldom that anyone campaigns for a new school or tries to find a better teacher, because these things are taken care of for him. No group of people ever get together and decide that the old church is too shabby and that they will get a new one. They wait till such things are done for them.

"It is not quite true to say that no one does these things. The coal company does them all. The essential characteristic of a coal-mining civilization, in West Virginia as well as in some other parts of the country, is the extent to which the employer, the company, controls things. It is a paternalistic, in some ways a feudal, civilization.

"Let us take a typical coal-mining plant. In the first place, the company owns practically all of the property. Usually it owns it for a considerable distance around the mine. It owns all of the buildings and the land on which they are erected. It owns the houses, the stores, the movie theatre, the Y. M. C. A. (if there is one), the school, the churches—in a word, the whole town.

"It employs the physician, and collects something each month from every miner to help pay him. It often guarantees the salary of the minister and not infrequently supplements that of the school teacher.

"The company is thus responsible for the welfare of the town. It is the sanitary officer with all his usual functions. It takes care of the roads, provides the lighting, determines the variety of amusements, and sometimes supplies the police protection.

"It can exercise supervision over persons coming into the town and events there. It can keep undesirable people out. It can, if it wants to, even censor the mail, since the Post Office is usually located in its general store and one of its employees is postmaster.

"Moreover, the company does not pay the people of the town as other industrial establishments pay their employees. It does not pay the men all that they earn in cash. Each payday the miner is handed a statement, which shows his total earnings for the period and the amounts he owes the company for various items.

"These items, or 'debts' as they are called, include the amount of his purchases at the company store. They include rent, a fixed charge. They include the lighting of his house, another fixed charge, and fixed charges for fuel, doctor, hospital, and the sharpening of his tools.

"The total amounts owed by him to the company are then subtracted from the total amounts due him, and he receives the remainder in cash. Thus, if he has earned \$80 during the fortnight and his debts come to \$43, he receives \$37 in cash."

From the strictly business point of view, the chief evil to be remedied is the irregularity of production. Some persons, among them Floyd W. Parsons, industrial writer, believe that much can be accomplished to alleviate this evil by providing increased facilities for the storage of coal. In an article in the *Gas Age-Record*, Mr. Parsons discusses this and other remedies as follows:

"Some contend that the cure for the bad conditions lies in the hands of the consumer, who can help greatly by arranging his purchases so that there will be a more regular demand for coal, which will result in a more regular operation of the mines. Others believe that the greater storage of coal is a partial solution of the problem. Then there are those who assert that in order to let demand overtake the present overdevelopment of our coal fields, we must enact legislation which would prohibit railroads from putting in sidings or arranging to serve new mines until after receiving from the Secretary of Commerce, or other prescribed official, a certificate of convenience and necessity similar to that now required by the nation's carriers before they are permitted to make capital expenditures for branch or main-line extensions, including material and equipment for same.

"Some of these suggestions would likely benefit the situation considerably. But all of them fall far short of anything like a complete solution of the problem, while, in addition, each of the suggestions has so many bitter opponents that without strong public support very little is likely to be ac-

complished in bettering conditions. The public has heard so much about coal remedies that it has grown apathetic and will not be aroused until something bordering on an industrial disaster actually happens. Such has been the history of the coal industry in this country from the very beginning, and there isn't the semblance of a hope that things are about to turn for the better. That we are riding to a fall goes without saying, but just when and where the smash-up will come is a matter of uncertainty.

"Storing coal during the summer months will help a lot. Forcing the miners' union to incorporate, bringing it under corporation and partnership regulatory laws, will also help a lot. The United Mine Workers' organization should be compelled to accept responsibility, and should be made to pay income and excess-profits taxes.

"But, after all is said and done, there are just two real solutions of the coal muddle. First, we must have a bureau of coal economics, an impartial and carefully selected Government committee, authorized to collect and disseminate coal statistics of all kinds. Instead of being a step toward Government control, this is the one and only step that will eventually prevent complete Federal regulation of our mines. Second, we must depend upon engineering skill and scientific knowledge to give increased profits to the owners, a greater annual income to the miners, and to supply fuel at a lower cost to consumers. At the present time, less than 200 pounds on an average, out of every ton of coal mined, is converted into useful work. The coal industry must follow in the steps of the meat packers, and start to refine coal and save the by-products, even to the last squeal of the article produced. If the people of the country wait for the coal industry to provide a solution of the problem, all they will get from their waiting will be industrial infirmity."

Far more drastic remedies than these have been suggested. Some persons believe that nothing short of Government operation of the mines, or at least close Government supervision, will solve the problem. Others say that the surplus mines of the country should be shut down; but not many persons are ready with practical suggestions as to how this can be done without injustice to the owners of those mines.

The problem of the nature of the work, and of working conditions among employees, is even more difficult to solve. Progressive mining corporations now are doing their best to give their employees the best possible conditions. Others, perhaps, will follow their examples in the future. No one is in a better position to help matters in this way than the operators themselves.

Bucket Shop Losses

(From page 1207)

form. Here again a sharp line of demarcation must be drawn between legitimate and illegitimate transactions. The making of contracts for the purpose and sale of securities, when, as and if issued, is, under certain conditions, absolutely proper. To prevent it would represent a financial hardship. The New York Stock Exchange accordingly does permit trading in securities 'when, as and if issued' under circumstances and conditions which the exchange considers proper and legitimate.

"Another point that has recently been made is that Stock Exchange members should be prohibited from speculating on their own account. Here again comes into play the problem of what is legitimate and what is not legitimate.

"The New York Stock Exchange recognizes that no broker may be permitted to speculate for his own account with the money or with the securities of his clients. All the rules of the New York Stock Exchange are intended to prevent any such practice, but there is no reason why a broker should be denied the right to employ his capital for the benefit of the country's development through new enterprises, provided that such employment of his own capital does not jeopardize his customers.

"The Governors of the New York Stock Exchange are constantly studying the possibilities of further reform and improvement in methods. We welcome suggestions from the public. We recognize fully that the Exchange cannot succeed, that it cannot be responsive to the public demands which are made upon it, indeed, that it cannot expect to be immune from drastic and unwise public regulation, unless it lives up to the highest possible standard of its obligations to an enlightened public sentiment."

HARVARD

Economic Service *for Executives*

will help you at this uncertain time when a dependable business forecast can prove of tremendous practical value.

Over 1,000 of the leading industrial concerns of America are following this Service regularly as a guide in planning their business moves.

Subscribers were warned of the recent depression fully six months before it occurred. They are now receiving forecasts of events for the coming months. Price \$100. a year.

A Master Key to the News of Business

OUT of all the flood of information that pours in on you through newspapers, trade papers, magazines and other sources, how are you to sort out the pertinent facts that bear on your business? Wouldn't a master key to the news of business be worth (literally) its weight in gold to you?

THE INDUSTRIAL DIGEST is precisely such a service. Out of all the news of the daily press, the trade and business press and all other sources, it selects, verifies, evaluates and arranges the business facts of importance and sets them forth digested and indexed—and interestingly presented.

THE INDUSTRIAL DIGEST presents the business fortnight in perspective. It offers the major executive in every field of business the opportunity to keep himself acquainted, with a minimum of attention, with important events in his own industry and in other fields of business as they bear on his own.

IT costs tens of thousands of dollars a year to prepare THE INDUSTRIAL DIGEST. But the subscription price to each executive is only five dollars a year.

This coupon will bring the service to you once every two weeks for one year.

THE INDUSTRIAL DIGEST,
25 West 45th St.,
New York City.

Please send your fortnightly survey of American industry and commerce to me for one year. I enclose five dollars, check or money order.

SEDGWICK

.... and when you're in a hurry

HERE speed is of the essence, where lifting and lowering equipment must quickly be procured, call upon Sedgwick.

Thirty years' experience has shown us what type of Hand Power Elevator, Dumbwaiter or Gravity Lift you are most likely to need, and chances are we have it in stock ready for immediate shipment.

In addition to those models which we carry in stock, our files hold the designs for hundreds of special machines. Obviously it requires the shortest possible time to manufacture machines from plans already drawn.

Our long experience exclusively in the Hand Power Lifting and Lowering field insures that installation, as well as construction, shall be done with utmost expedition.

Write and ask us to prove we can help with your lifting and lowering problems.

For lifting
and lowering—
SEDGWICK

*In the home as well as in industry, Sedgwick
elevators are now made daily and to more
than a quarter of a century. Sedgwick Hand Power
Dumbwaiters and Gravity Lifts are the
most trusted machines and tested to perfection.*

SEDGWICK MACHINE WORKS

*For 30 Years Manufacturers Exclusively of Hand Power and Gravity Lifting and
Lowering Equipment.*

Pins for Maps and Charts

Solid Colored Glass Heads

AVAILABLE IN 16 DIFFERENT COLORS

All Illustrations Are Full Size

The Most Common Size used is this special head pin.

For Congested Maps or charts and holding territory or route cord in place use this pin.

Glass Spot Pin. The spot is fused in the head of the pin. It cannot come off.

Enamel Spot or "Ring Pin." Spot is enamelled on the glass. This and the glass spot pin photograph as a ring.

Enamel Spots can be furnished as a DASH or CROSS if desired.

Triangular or Square Head pins are used where the 16 colors do not furnish sufficient variety. They also help color-blind users. These pins show distinctive shapes when photographed whereas some colors photograph the same.

Spiral Top Pin. Furnished with card in any of the 16 standard colors. Useful where much data must be written out.

Signal Flag. Made of celluloid. One side glossy, one can be written on. Useful for indicating special attention or where a flag is preferred to a pin.

Series 6500

Series 6600

Series 3400

Series 3400

Series 3500

Series 3600

Numbered or Lettered pins made up to order in any of the 16 standard colors. Dark colors with white letters photographed as black circles enclosing the figures. Use size of pin admitting maximum number of figures required. These numbered pins used in sets 1-31 to indicate days of the month. Also alphabet sets A-Z.

Oil Well Pin. Shape resembles oil well derrick. Can be supplied with two-colored head.

Series 4500

Map Ring. Colored celluloid ring for slipping over head of pin to indicate additional fact.

Series 550

Beads. Uniform in size and color with 3/16" and 3/32" spherical map pins respectively. Can be used with pin to show additional fact or strung on long pins to show accumulation or quantity at one spot.

Series 650

Rough Surface Glass Pins to write on. Pencil will erase and ink can be washed off from these pins so they can be used again and again.

Series 3650

Series 3450

Series 3350

EVERY CONCEIVABLE TYPE OF MAP MARKING DEVICE. Over 30 varieties and 16 colors of each made in our own factory.

RECORDS MADE WITH EDEXCO GLASS HEAD PINS ARE PERMANENT

You will never be annoyed by colors fading or peeling off the pin. EDEXCO Pins are made with heads of solid color glass. The color is fused in the glass when it is made—not painted on afterwards.

SERVICE

We are always glad to work with you to help you get at the exact key or color scheme to best cover your requirements.

Plan Your Sales Campaign on "Namapco" Washable Maps

MOST of the big, successful sales campaigns are first planned on maps.

"Our first step in planning a campaign in new territory," says a successful sales manager, "is to secure large maps of the city or state. The location of dealers is indicated by different colored tacks. Then the sales force starts out. Our system of tacking the maps tells us at a glance the exact status of every dealer. By changing the tacks from day to day, we have a constant check on the condition of every territory, simply by watching our maps and keeping them up-to-date."

"Namapco" washable maps are ideal for sales and territorial work because, in addition to using the tack system, you can mark on them with crayon, ink, or water colors—outlining territories, indicating salesmen's routes, marking down sales quotas, sales totals and other important data. When changes in the marking are necessary, simply wash it off with a sponge or damp cloth, or erase with art gum. The surface of the map is left smooth and clean, and the detail is not injured in the least.

*Multi-Unit System of "Namapco" Washable Maps
in office of Brunswick-Balke Co.*

*Multi-Unit System of "Namapco" Washable Maps
in office of Monroe Calculating Machine Co.*

"Namapco" washable maps are used by many of the leading firms in the country in planning and keeping check on sales and advertising campaigns. Among these are Studebaker, Sherwin-Williams, Armour, Pillsbury, U. S. Rubber, Kohler Co., Monroe Adding Machine Co., Brunswick-Balke Co., Quaker Oats, General Motors, Vacuum Oil Co., etc., etc.

Small Washable Maps for Multi-Unit or Map Cabinet System

The map systems shown here are the large size Multi-Unit, in which our large business maps are displayed. The wings are 50 x 48 inches. We can also supply smaller maps, size 21 x 28 inches, with complete index on front surface, which are suitable for use either on the smaller size Multi-Unit system (wings 29 x 29 inches) or in map tack cabinets.

With the small size Multi-Unit System, we furnish graphic chart sheets 8 x 27 inches in size, which are mounted on the wings either below or at the side of the map and index. This graphic chart, on the same surface as the map, makes it easy to keep records and supplement the information shown on the maps. The maps are complete and accurate, and have the washable surface.

*If you will tell us what territory you cover, we shall be glad to recommend a map system that will give you maximum service. Address

It's Time to "Pick Up the Pilot"

*A problem for the President, General Manager,
Director, Secretary or Treasurer.*

Each business today is headed for a new port:—

"The commonly accepted but traditional and antiquated methods of cost accounting, prevalent in so many plants, are falling down under the pressure of modern manufacturing methods. These accounting methods, disguising as they do the real costs, and presenting instead fictitious costs whose real values are thoroughly concealed, have no place in the modern American intensive production manufacturing plant. *What our managers need is not a cost system whose primary purpose is to lend itself, through the accounting department, to a financial audit, but a cost system which is primarily designed to reveal true costs in time to control them and to prevent them from becoming excessive.*"

THE EDITORS,
Industrial Management.

Methods of production planning, of accounting, and most emphatically of cost determination, perhaps efficient in other days, have now become an inadequate *collection of habits—rut-running habits.*

Can your decisions and policies in meeting present conditions, then, be other than fettered by such habits—these "ghosts of yesterday"?

The solution lies not in revolution, but in evolution; through a fresh point of view and the application of sound economic principles.

Your accounting, costs, production planning and sales, under our consulting supervision (based upon an experience of 30 years) will reveal new profit opportunities. We can arrange a service to fit your particular needs—and pocketbook. "It's time to pick up the pilot." At least, let's talk it over.

Our bulletin, "Straight Talk," an exceedingly informal two-minute chat on management problems, will assist executives who have ambitions to satisfy. Your request on your letterhead will bring a complimentary copy.

Economical Handling of Barrels and Drums

Cedar Hill Terminal of New York, New Haven & Hartford

Uses a New Type of Truck Built by

Lansing Company and Completely Hyatt Bearing Equipped

For the economical handling of barrels and drums the New York, New Haven & Hartford Railroad is using a new type of three wheel truck evolved by the Lansing Company. This is a two wheel truck with a caster wheel between the handles.

The new three wheel truck is loaded just as any two wheel truck, and is then dropped until the caster wheel rests on the floor. The loaded trucks

easy running, their lubrication saving and their durability.

The rollers of the Hyatt bearing provide a true rolling motion in place of the rubbing friction of plain bearings, so that one man can handle twice as heavily loaded trucks without extra exertion and tractors can pull more trailers per train

The bearings are enclosed in the wheel hubs, providing a space for lubricant which need be replenished only three or four times a year — a real saving in oil and labor.

Near view of a three wheel truck.

The easy rolling element of the Hyatt bearing

The tough, resilient steel rollers are designed to operate correctly without appreciable wear even after years of hardest service.

Whatever type or make of trucks you are using, these advantages can be secured by specifying that they be Hyatt equipped. Practically all representative truck manufacturers are in a position to furnish their trucks equipped with Hyatt roller bearings.

Hyatt Roller Bearing Co., New York, N. Y.

Industrial Bearings Div., New York
Motor Bearings Div., Detroit
Tractor Bearings Div., Chicago
Pacific Coast Div., San Francisco

The new trucks are equipped throughout with Hyatt roller bearings, making them easy to move either by hand or as trailers and insuring their dependable operation for years without necessity of bearing adjustments or replacements.

Whatever improvements are contemplated in your trucking systems it will pay you to give careful consideration to the bearings. The use of Hyatt roller bearings makes possible material handling at the lowest cost per ton because of their

This is the way they haul barrels at the Cedar Hill Terminal of the New York, New Haven & Hartford on three wheel trucks equipped with Hyatt roller bearings and made by the Lansing Company.

Of the three factors entering into the cost of any manufactured product—material, labor, and factory overhead—management can exercise the greatest control over factory overhead. In this one factor lies the greatest opportunity for reducing the total cost of goods.

Curiously enough, in some establishments, overhead gets even less attention than labor or material costs. And this burden on the organization frequently proves to be the undertow that drags the figures from the black over to the red side of the ledger.

We specialize in charting costs, reorganizing manufacturing plants and improving production methods to the end that overhead may be as low as is consistent with good management.

Would you like to know how we have helped other manufacturers get out of the undertow?

The Business Weathervane

A Summary of Expert Opinion

Economic observers generally agree that though the summer depression is affecting business unfavorably, fundamental conditions are all favorable to a steady increase in business in the fall.

The **Harvard Economic Service** believes that "it is noteworthy that the June improvement took place during the third month of the coal strike, and with the northern cotton industry still suffering from labor trouble of even longer duration. Advance under such conditions shows clearly the impetus of the forces making for progress and warrants the expectation of an

acceleration of the upward movement when these retarding factors are removed. The continuation of the improvement begun in February corroborates the evidence furnished by easy money and the rise in speculation that the present advance is a major upward movement of the economic cycle.

"Business sentiment at the end of the half-year is becoming more optimistic, despite such adverse influences as labor troubles in the United States and financial disturbances in central Europe. Earlier doubts concerning the improvement shown are giving way to the conviction that a substantial recovery is under way, and only its extent and permanence are called into question. Doubt as to the reality of the improvement is now met by such persuasive evidence as the unprecedented building activity, the return to more normal production in the iron and steel industry, the sustained increase in freight car loadings, the decrease in the number of failures, and the advance in wholesale prices since the beginning of the spring. Such clear signs of improvement have followed, as in the past, the easing of money conditions and advance in speculative activity which were the most conspicuous developments in the first quarter of the year."

J. H. Tregoe, of the **National Credit Men's Association**, believes that the favorable factors are: 1. Economy in the raising of the present year's crops. This economy will be a tremendous help to the farmer and increase his purchasing powers. It is already reflected in increased sales by mail order houses. The agricultural sections are looking up. With the farmer back in the market business will be greatly accelerated and strengthened. 2. The production of basic commodities is on the upward trend despite the strike. The pro-

duction of pig iron and steel ingots is showing improvement. 3. Railroads are coming into the market. Freight cars ordered up to June 3 total 80,000—three times the number ordered in 1921. If continued at this rate an output of 190,000 freight cars in 1922 is promised. Other equipment is being bought by the railways, making an encouraging factor in the situation. 4. Railway earnings show a little improvement. The gross returns are less than last year, but reduction in operating costs have put the net earnings on the favorable side. 5. Renewed volume of trade is reflected in carloadings and by other indexes. There is a decrease in some lines and in some districts, but on the whole, the volume has increased. 6. Construction is still active as indicated by contracts awarded recently. The figures for May were the largest ever recorded for that month in the country's history. The figures for the

(Indianapolis News)

Beginning to worry him.

first five months of the year are 61% larger than the figures for the same period of 1920. This construction is mostly residential, but business and industrial building is also improving. 7. Unemployment is decreasing. A marked increase of employment is recorded in automobile, paper, car building and repairing. Unemployment is recorded in other lines, but on the whole there is little enforced idleness. 8. A continued improved mental attitude on the part of the people. This is a good indication and helps in our recuperative process.

(Turn to page 1320)

Wanted: Action

THE facts in the coal situation are these: Coal production has already been hampered by a strike lasting 15 weeks. Anthracite production at the present time is practically zero. Bituminous production is two and one-half million tons a week, less than consumption. On August 1, there will be a reserve of approximately 23,000,000 tons of bituminous coal from which must be drawn 10,000,000 tons a month, if consumption is not restricted.

In other words, in less than 10 weeks every industry in the country will be facing empty coal bins. A coal famine actually exists at the present time, and every week of famine is certain to add to the price of coal to manufacturers.

From these facts THE INDUSTRIAL DIGEST draws these conclusions: At whatever cost, the coal strike must be settled unless industrial activity in the United States is to be slowly throttled to death. Such a disaster must not be permitted. There appear to be three alternatives: (1) A peaceful compromise will be effected between the union leaders and the operators. (2) Either the operators will give in or the miners will return to work on terms dictated by the operators. (3) The Government will step in and operate the mines.

For 15 weeks the first alternative has not proved successful.

Although we do not believe that the miners represent an irresistible force or the operators an immovable object, neither group has modified its demands in any way since the beginning of the strike, and it does not appear that they will.

If manufacturing is to go on and if workers are to continue to draw pay envelopes every week, there is only one solution: the Government must step in. The Administration has progressed from inactivity to suggestion, from suggestion to requests, from requests to threats—and nothing has been accomplished.

THE INDUSTRIAL DIGEST believes that the time for words has passed. We believe that the country demands action. We ask the Government to take immediate and decisive steps to operate the mines. Operators should be compelled to open their mines and miners should be forced to return to work by injunctions. The terms can be settled just as well after production is resumed as when the mines are idle. We believe that Government action can be hastened by manufacturers if they will get in touch with their Congressmen, point out the importance of a prompt settlement and demand that coal mining be resumed before our factories and mills shut down. We urge our readers to take this step promptly and forcefully in the belief that it will help to correct a situation which is even now threatening the very life of business.

What of the Coal Strike?

PRACTICALLY speaking, there has been no change in the coal situation, although President Harding has requested operators to open their mines, demanding that both State and Federal protection be given to every man willing to work. Observers generally agree that the strike is no nearer a settlement than on April 1. Union labor's attitude is expressed by President Gompers of the American Federation of Labor: "The miners who are on strike are not going to dig coal until the strike is ended. The non-union miners are and have been at work and their number cannot be materially increased. The army may go into the mining districts but the army is not composed of coal miners. The operators' refusal to budge is influenced by the fact that while the reserve supply of coal is dwindling at an alarming rate, prices are beginning to rise and the strike will not affect the amount of coal to be

(Philadelphia North American)

A situation bound to develop sooner or later.

burned, in any event so that the situation does not affect sales. It will be recalled that in the case of the strike during the Roosevelt Administration there was a deadlock of 23 weeks before action was taken. Furthermore the strike was not settled until cold weather had forced public opinion to a general clamor for coal. If the present strike runs into cold weather thousands of manufacturers and factories will be compelled to shut down on account of lack of fuel."

Attorney General Daugherty after a Cabinet conference recently made the following statement: "Developments in the rail and coal strikes indicate the existence of a definite relation between the strikers in the two industries. Whether this relation is inspired or conspired, I am not now prepared to say."

Rail Strike Not Likely to Spread

CERTAIN it is that the rail strike is becoming daily of greater assistance to the

in Perspective

miners who are out. Industries that were hard hit by the coal priority orders two years ago are becoming apprehensive once more. With a certain shortage of cars running up in the fall, priority shipments will unquestionably be necessary to avoid confusion.

The rail strike has also reached a dead center. In addition to the 300,000 shop men who went out originally there are now 8,000 stationary firemen and oilers out. Although there has been no official walkout of the 400,000 maintenance-of-way men, reports from all over the country indicate that many of them are leaving their jobs. In addition, labor circles report that the 200,000 railway clerks are voting in such a manner that a strike is inevitable. Every week that the strike lasts will make the freight tie-up in the fall just so much worse. The only possibility that the strike will not spread beyond the 308,000 men now out lies in the recent acceptance by the railroad executive's proposal that employees who are members of other unions shall not be called upon to do work of the striking shopmen. This apparently removes the most immediate source of danger that the strike will spread.

Unions Showing Bold Front

THERE has been too much violence in connection with the rail and coal strikes here according to editors of leading papers.

It might be supposed that under the terms of the Coronado decision rail union executives would be troubled as to the possible damage suits that might be filed. At present there is pending against the strikers for interference with transportation damage claims of over two million dollars.

The United Mine Workers of America apparently learned no lesson from the Herrin massacre since their members again took part in a wholesale murder in West Virginia. Outbreaks on railroads have not been so frequent, but there are widespread reports of damage to property and interference with train schedules. As a matter of fact the rail unions are counting upon the fact that rolling stock is not in good shape in order to win the strike. Bert M. Jewell, president of the Railway Employees Department of the A. F. of L., stated in a recent speech to strikers: "The economic condition of the country is on our side. Time is fighting for us. The demand for freight traffic is increasing steadily all over the country. The railroads realize that there must be a tremendous coal traffic before December in order to supply domestic and industrial needs of the country. On June 15, 14.6% of the freight cars of the country were in bad order. This is more than twice the normal percentage. Locomotives on most roads are also in bad condition."

The effect of such a statement on strikers is obvious.

(New York World)

Soft music by the snake-charmer.

(Brooklyn Daily Eagle)

This threatens to become chronic.

*How long will the building boom last?
Here are facts on which to base your opinion.*

Going Up Together:

Buildings and Business

Construction activity affects every line of business—it influences prices of commodities, is largely responsible for the employment situation and practically determines rents—business men should watch the building barometer closely.

WE are in the midst of the biggest building boom the United States has ever known. Throughout the country there is bustling in lumber yards and brickyards, chisels are clanking in quarries, steel mills are rolling out structural forms, carpenters are banging away with their hammers, masons are wielding their trowels and painters their brushes; and more structures are being erected than at any previous time in the history of the nation.

A boom—or a depression—in the construction industry affects all other lines. Construction is one of the key industries of the nation. It uses the products of about one-fourth of all the persons in the country who are engaged in manufacturing. It consumes about nine-tenths of all the iron, copper, zinc and lead produced. Normally, it is estimated, construction absorbs about half the new capital accumulated in the country every year. It affects all other industry through its influence on rents. The great number of persons who engage in it form an important part of the consuming public.

Construction has felt with unusually great weight the problems which afflict industry in general. It has experienced its full share of labor difficulties. It has been forced to deal with a scarcity of materials. It has been the subject of Govern-

ment inquiries, and has suffered from much malpractice on the part of those who engage in it. Therefore its sensational recovery, at a time when most lines of business, though somewhat improved, are still languishing, is especially interesting.

The building industry was one of the first to feel the post-war depression. A chart prepared by the Associated General Contractors, comparing the fluctuation of pig iron production with the variation in the number of building permits issued throughout the nation, shows that activity in building started to decline in 1920, eight months before pig iron production began to sag. In fact, when the iron output started its downward movement the drop in construction was almost even. In November, 1920, the number of permits issued began to rise, and with occasional temporary relapses it has been on the upgrade ever since.

The increase in construction in 1921, however, could by no means be called a building boom. The total contracts reported in 1921 by the F. W. Dodge Co. for 27 Northeastern States was only \$2,359,018,000, 8% less than the total for 1920. In other words, the 1921 record, while better than that of the latter part of 1920, was still so poor that the activity in the first part of 1920, before the depression, was sufficient to bring the entire 1920 record higher than that of 1921.

At the beginning of this year the real boom started. In January the Dodge company reported that contracts were 49% ahead of those for the same month last year, and the contemplated work bulked larger than at any time since the previous April. In February the contracts awarded were 7% ahead of January and 73% ahead of February, 1921. In March more contracts were awarded than in any other month except April, 1920, which was one of the big months before the depression. Spring was here, and outdoor work was going on in earnest.

In April, 1922, the contracts awarded in the 27 Northeastern States covered by the Dodge reports reached the unprecedented sum of \$353,192,000, making April a record month for all time. The April record was 20% higher than that of the preceding month, and 60% ahead of April, 1921. The total contracts reported by Dodge for the first four months of the year amounted to slightly less than a billion dollars. This is about equal to the record of the first four months of 1920, before the depression.

This Year Will Break Records

MAY and June of this year carried the building boom even higher, and led to the expectation that the total for 1922, barring accidents, will be far greater than that of any other year. The May record of contracts awarded was 3% larger than that for April. Up to this time the record-breaking building had been confined almost entirely to the Eastern States. The West was coming merrily along, but it was lagging behind and not breaking all precedents. In May, however, all parts of the country broke records.

About 40% of all this building is for residential purposes. About 15% is for business, and about 8% for industrial purposes. The proportions remained approximately the same from month to month.

Behind the building revival is the tremendous demand for homes. If it were not for the housing shortage from which we suffered throughout the war, so remarkable a recovery in the face of adverse conditions would not have been possible to the construction industry. Thus even the housing cloud had a silver lining: the shortage of buildings made possible the construction boom, which in turn contributed largely toward the general industrial recovery (however slight) that has made itself felt this year.

The housing shortage, apparently, will furnish the stimulus for building for many years to come. Of 24,351,676 homes in the United States, 54.4% are rented, 28.2% are owned outright, and 17.5% are owned under mortgage by occupants. According to John Ihlder, manager of the Civic Development Department of the Chamber of Commerce of the United States, the shortage at the beginning of 1922 was equal to three years' pre-war normal production. "So great has this shortage become," he says, "that even if we begin on its reduction now, it will take us 12 years working at 25% above normal to provide as adequately for our population as we did before the war."

"Of course there will be a regular 25% above normal house production during either 12 years or a shorter period," he continues, "but such a statement enables us to visualize the situation more clearly, just as do the estimates which precede

it, rough as these necessarily are because of our nationally characteristic lack of definite statistics.

"These conclusions are substantiated by the building permit figures, running back to 1914, from 24 cities of 100,000 population or more situated in every section of the country, and therefore taken as fairly typical. Of these cities 13 issued more building permits for dwellings in 1921 than in any one of the years 1914, 1915, or 1916. Yet the total number of permits for dwellings in all the 24 was less by 1642 than in 1914 and by 4982 than in 1916.

"From 18 of these 24 cities it has been possible to secure figures in greater detail, showing the type of dwelling constructed, whether one-family, two-family, or multi-family (apartment and tenement houses). Here the effect of the optimistic spurt in house construction early in 1919 becomes more evident. We had persuaded ourselves that when the war ended house building would begin. And so it did. But it slowed down again under the pressure of economic conditions until in 1920 it approximated the low level of 1918. During the optimistic era, however, these cities issued permits for nearly a normal number of houses, 22,877 in 1919 as compared with 23,133 in 1914, 25,309 in 1915 and 26,654 in 1916. The proportion of multi-family houses to one-family houses, however, was not the same as in pre-war years, though more like it than has been the case since."

In spite of the greatly increased building activity during the last six months, in this country, the housing shortage as a whole is still somewhat more than two and a half years' production, according to John Ihlder, the manager of the Civic Development Department of the Chamber of Commerce of the United States. In the opinion of Mr. Ihlder, the situation varies in different cities. In some cities the shortage is estimated as nearly four years, while in others it is approximately one and a half years, and in some cases even less.

The labor situation in the construction industry is unlike that in any other. A great variety of highly skilled craftsmen are used in building. These trades were among the first to organize, and their unions are among the strongest in the country.

Corruption in the Building Trades

LEGISLATIVE inquiries in New York and Chicago the past few years have revealed a condition of corruption in the building trades unions that has astounded the entire country.

The two factors have been operating to slow up construction—weakening rent levels and increasing construction costs—continued to affect the general building situation adversely during May. In centers where residential construction has been heavy considerable recessions in the general level of rents continue to be reported. Although the rapid increase in the

number of residential quarters will undoubtedly benefit the general public, it cannot fail to weaken the inducements to build at prevailing cost levels. Costs at present fail to show any decline in comparison with the decrease in rentals. Their general trend, on the contrary, appears to be upward. The two chief reasons for this are scarcity of materials in centers of the greatest building activity, and scarcity of skilled workers—which results in higher premiums being paid for these workers and resultant mounting building costs.

If the revival in the building industry continues smoothly, the housing situation will be alleviated, and business in general will be stimulated. But the path of the building boom is not

Good riveters are more to be heard than seen. A close-up of riveters snapped at work on the steel beams of a new skyscraper.

entirely smooth. It is threatened in particular by one outstanding danger: the danger that labor trouble in the industry may halt production and send building costs up to an absolutely unworkable level.

The entire construction industry was discredited by the revelations of the existence of grafting labor leaders, who combined with corrupt employers to keep building costs high and maintain monopoly conditions in the industry.

More Housecleaning Needed?

THE object of these investigations was to clean up the building industry. To some extent they succeeded. They resulted in the jailing of a few guilty persons, and—more important—they awakened the honest employers in the industry to a realization that they must stick together to maintain the reputation of their trade. But, according to W. A. Starrett, an eminent New York builder, the seeds of further trouble still lie in the unions.

"While many causes contributed, the system under which unions are conducted could hardly have led to any other result than the disclosures have revealed," says Mr. Starrett. "In fact, it may truly be said that the contributing causes merely accelerated an inevitable climax. Moreover, it is well known by those who have taken the trouble to inform themselves,

into an appalling obscurity, judged by the standards of government banking, corporation management, or, in fact, any known form of orderly business administration. As for the average union election, it is a crude and haphazard affair, if the standards of election as developed in free governments are any criterion.

"It is here that we commence to get at the root of the trouble, and here that we find the same human fallibility that governs in all other walks of life. The fruits of human greed, domination by the self-seeking, corruption and stealth, assert themselves and flourish in the rich soil of unaccountability, which unionism has so fatuously pursued in the mistaken belief that by this means they were baffling their opponents.

"The condition in which labor finds itself today proves for the thousandth time that certain laxity of method produces about a certain result, and that all the sentimental appeal to public sympathy for the downtrodden, the sanctity of labor, and all other high-sounding phrases are merely illusive gestures in the face of the inexorable law to which they do such violence in their scheme of organization. A consequence of inside politics, the stultifying of free and uncoerced voting and gang rule are inevitable concomitants of the policy that many labor unions in the past have allowed to flourish.

"In the revelations of its own shortcomings and the opportunities afforded for a clean, businesslike internal reconstruction, organized labor in the building industry today stands at the threshold of the greatest opportunity that has ever presented itself. Waning public sympathy could almost imme-

that the culminations of the last year are only exaggerated repetitions of former building labor upheavals, which, while they occurred without the accompanying glamour of an economic crisis, were nevertheless the outcome of the same forces that so inevitably produced these latest scandals.

"The frequent recurrence of these upheavals, and the even more significant fact that the conditions revealed are on the increase, and that no temporary palliative, such as the conclusions of the Lockwood Committee promise to afford, will have any lasting effect, leads to an inquiry into the underlying causes.

"We hear so much about vast funds belonging to this or that labor organization, and the election to office of this or that great labor leader, that we give little consideration to the details. Whence these vast sums? How are they administered, and what of the individuals who control them? What is their experience and fitness, and what accountability do they give? The facts seem to be that the questions of labor finances and labor leadership are all bound up in one, and both disappear

diately be revived by labor unionism striking from its body the parasites of internal corruption and its twin, that spirit of law defiance which so menacingly resembles Bolshevism.

"Will the next cycle of building labor turn forward or backward? It seems trite to say that the unions hold their own destiny in the hollow of their hand, for even such a platitude needs further definition. Perhaps it would be more accurate to say that for the first time building trades labor, as now unionized and controlled, has been brought squarely before the bar of public opinion. The question is: Will it truly appraise the probation upon which its system is to be put by public opinion, or will it revert—shall we say—to type?"

Public Co-operation Wanted

OTHER builders do not question the future so gravely as does Mr. Starrett. Noble Foster Hoggson, president of Hoggson Bros. and a director of the Associated General Con-

Can the public be awakened in time?

combat self-satisfaction and conservatism. The electrical industry, the automobile industry, and the motion picture industry are examples of what can be accomplished with industrial youth. Youth always means enthusiasm. In construction we have age—almost old age. It will be much harder to generate enthusiasm, to secure the virility and freshness of viewpoint which an industry awakening to new consciousness of responsibility should have.

"But though it needs enthusiasm and a new viewpoint, it must, because it is dealing with long-entrenched practices, with conservative policies and conservative men, carefully avoid, in its early days, controversial subjects. There are many rocks on which it could instantly go to pieces. If it will choose only those subjects on which it is apparent that agreement can be reached, then, when all the elements have learned to work together and to have confidence in each other, it will be soon enough to take up those difficult problems that right now would raise destructive controversy.

"Judging by the men who have participated in the organizing work and who were at Washington, high purpose will be combined with virility and with a studious avoidance of needless and harmful controversy. The council is well launched."

West to Spend Four Billions

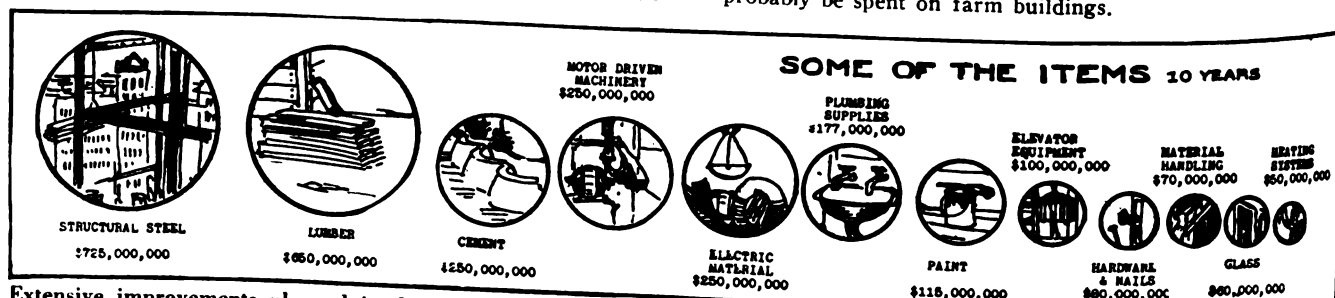

IN the future the West will share fully in the building boom, in the opinion of the *Journal of Electricity and Western Industry*. According to this magazine, more than four billion

dollars will be spent for construction in that section of the country during the next ten years. It bases its estimates on the records of previous years and on estimated population growth.

"Building records for cities in the West in which the building permits amounted to over \$1000 show that \$233,828,300 was spent in the construction of homes, commercial buildings and factories in thirty-four cities of this class," this magazine says. "The population of these communities amounts to 2,863,337 people, which gives an average expenditure of \$81.66 per individual for building construction. This figure was applied to the population of all cities of over 5000 population in this district, which gave a figure of \$346,210,941 for 1921 in all cities of the eleven Western States. Allowing for the normal population increase, this becomes \$4,200,000,000 to be spent in construction during a ten-year period. Applying the accepted ratio of homes, commercial buildings and factories, we get:

\$1,700,000,000....for homes in the next ten years
830,000,000....for mercantile structures in the next ten years
830,000,000....for office buildings
900,000,000....for factories

"To these sums, in estimating the total expenditures for building purposes, should be added \$675,000,000 which will probably be spent on farm buildings.

Extensive improvements planned in the eleven Western States during the next ten years will call for the use of great quantities of construction material.—(*Journal of Electricity and Western Industry*.)

Materials the West Will Use

THE following is an estimate of the cost of the materials which will be used in buildings in the West during the next ten years:

Foundation	\$ 55,260,000
Structural frame	720,980,000
Lumber, millwork	624,464,000
Concrete walls, fireproofing	177,105,000
Roofing	42,914,000
Bricks, mortar	94,390,000
Plaster, laths	155,702,000
Plumbing	159,999,000
Paint	93,586,000
Glass	56,660,000
Marble	48,057,000
Hardware, nails	79,025,000
Electric materials	104,831,000
Flooring, tiles, etc.	40,461,000
Ornamental iron	70,730,000
Sheet metal	14,800,000
Heating system	44,072,000
Elevators	100,780,000
Conveyors	5,000,000
Pneumatic tubes	13,000,000
Chutes	10,121,000
Vacuum cleaning system	1,600,000
Sprinkler	25,000,000
Sidewalk lights	2,526,000
Auxiliary power plants, etc.	2,988,000

"An attempt was made to get a definite estimate of the equipment which will be required to outfit these buildings. No statement could be obtained from furnishing houses or others supplying office and home equipment, but a field survey of factories and business houses has offered the basis for what is believed to be a reasonable guess in the matter of future requirements. It is accepted as a general average that the costs of furnishing the average home are in the neighborhood of 15% of the cost of the building. From \$150-\$250 per room is a modest figure, which for an 8-room, \$10,000 house means \$1200-\$2000. It has been pointed out that many of those moving into new houses bring their furniture with them

and add only a few pieces. The house which they vacate must in that case be furnished by the new tenant—or, if the same process is repeated here, at least, with the increase of so much lodging space to that already existing in the community, an equivalent number of rooms must somewhere be furnished new. If it be considered that each new tenant down the line moves into larger quarters, so that the final newly furnished quarters prove to be a very modest workingman's home, it must nevertheless be considered that each tenant will have had to purchase some additional equipment, so that in the end, the amount will be roughly the same. An attempt was made to estimate how many families may bring their furniture with them from the East, but the number appeared to be so small that the deduction from this source need not be considered. So long as the family moves from one part of the West to another, the above analysis holds roughly true.

"In order to allow for all these factors, however, the figure of 10% of building costs was assumed as a furnishing expense. This gives \$170,000,000 for home furnishings. In the case of commercial buildings there is still less chance of equipment being brought from a great distance and 10% flat has been allowed as a very modest estimate of furnishing costs in office buildings and mercantile establishments. This gives \$166,000,000 for this field. An electrical wholesaler estimates that \$30,000,000 will be spent in electrical equipment in the West every year, or \$300,000,000 in ten years.

"The equipment needs of factories have been studied in considerable detail. Typical plants have been analyzed and their proportional figures applied to census returns in a typical field. The expenditure for machinery and factory equipment in the factories of the West in the next ten years will probably amount to some \$2,222,450,000 for the industries analyzed. On the basis of capital invested in the industries investigated, which is approximately 50% of the total capital in all industries, this would mean roughly \$4,400,000,000 in equipment for all industrial plants in the West."

This prediction may or may not come true. In any event, it shows how broad are the effects of a building boom upon business in general, and how extensive and continuous the boom is expected by some authorities to be.

The High Cost of Loafing

Workers in this country lose \$5,000,000 a day in wages on account of labor troubles—who pays this enormous strike bill?

OVER all industry—and especially over the building trades—hangs the spectre of labor trouble. Building contractors, in making estimates for a structure, always add a percentage, sometimes as high as 50%, for contingencies; and nine times out of ten the main contingency is a strike, or the threat of a strike.

Other industries also suffer from the same disease—perhaps in a lesser degree, but still they suffer. Strikes are the great bogies of modern industry.

Business men know this. Workers know it. The public knows it. Yet strikes multiply.

If the American people—workers, business men, farmers, and all—decide that this condition must stop, they will find the means of stopping it. Evidently they have not so decided. Instead of concerted attempts to end strikes, each month brings forth a new collection of threats. The employers defy the workers. The workers defy the employers. Apparently both sides think they can gain more by a condition of industrial war than industrial peace.

THE INDUSTRIAL DIGEST submits that no strike is worth its cost. Strikes cost employers and workers more than either side can hope to get out of them. After the anthracite coal workers, some years ago, had won a wage increase by a

strike, it was computed that it would take them 15 years, if they continuously saved every bit of the increase they had won, to get back the wages they lost while the strike continued.

A statistician of the National Industrial Conference Board has computed that American workmen now on strike are losing something like \$5,000,000 a day in wages. The loss to non-striking workmen who have been thrown out of their jobs because of the strike is probably just as large, but no data are at hand from which to compute it.

An Industrial Army A. W. O. L.

ABOUT 1,250,000 men are now on strike. Roughly 80,000 of them are textile workers, who have been out since the early months of 1922; 155,000 are anthracite coal miners, who have been out since April 1; 573,000 are bituminous coal miners, who have also been on strike since April 1; 400,000 are railway shop workers, who have been out since July 1; and the balance are an assorted lot of building-trade workers, clothing workers, etc. One is safe in assuming at any time, year in and year out, that about 20,000 workers in the clothing and garment trades are on strike. Sometimes they are boys' pants makers, sometimes dress workers, sometimes cap makers, sometimes millinery workers, and sometimes another kind of

needleworker; but some of them are always out because of a quarrel with employers.

Lost: Ten Million Hours

ASSUMING an eight-hour day, these 1,250,000 strikers represent a loss amounting to 10,000,000 man-hours every day. It would take 100 men, working continuously for 300 days a year, five years to offset a single day's loss at this rate.

This is only one side of the picture. The other is the loss in production to industry, and the loss in profits to employers. These cannot be computed. Figures on the loss of production due to the coal and textile strikes, for instance, cannot be found, for there is no way of telling how much would have been lost in these industries regardless of the strike, because of seasonal shutdowns and lack of business. In the absence of reliable figures all we can say is that the losses are tremendous.

Marshall Olds, in his book *The High Cost of Strikes*, has attempted to compute the price which industry and the public pay for industrial warfare. He believes that strikes were the basic cause for the tremendous post-war increase in the cost of living.

Mr. Olds points out how a strike of dock workers in New York was expensive to a far greater number of persons than were involved in the controversy. The strikers tied up the docks of the Clyde, Mallory and Old Dominion steamship lines. An important part of the freight of these lines consists of fresh vegetables raised in the South for consumption in the North. The strikers walked out just when the biggest run of this class of freight had started.

The effects of this strike are worth tracing, because the process is clearly illustrative of the manner in which transportation strikes exact their toll of the community. A short while after the strike was declared New York was sorely in need of potatoes. A special attempt was made to get a cargo through. The vegetables were brought safely to the dock, within 300 yards of the warehouses—but these last 300 yards were blocked by the strikers. Finally a lighter was secured and the potatoes were secretly moved aboard it. The lighter was towed down the Hudson River and up Newark Bay to Harrison, N. J. Then trucks were employed to carry the potatoes from the lighter to the Erie Railroad, which carried them to New York. The cost of this roundabout transportation was \$4 a barrel. New Yorkers paid the price. They were glad, at that time, to get the potatoes at any cost.

There was no real gain from the additional \$4 which were added to the cost of those potatoes. It was purely economic waste. Items such as these must be added to the schedules of wages and production lost, when we calculate the cost of strikes.

A strike need not be in a fundamental industry in order to

be costly. Railroad, coal, steel and building strikes naturally spread their disastrous effect more widely than disturbances in trade which are less important to industry in general; but even a walkout of a few thousand printers can cut deeply into the economic life of the nation.

It is estimated that more than 1,500,000 workers suffered serious losses of wages for three months in the winter of 1919-20, because 2000 New York printers all went on a vacation at the same time. The strike came in the fall, when the print shops of the city were preparing great quantities of mail-order catalogues and other sales literature. The great New York mail-order houses sell to about 10,000,000 customers, scattered throughout the country, and their sales depend almost entirely upon their catalogues. In addition to the regular mail-order concerns, great numbers of jobbers and manufacturers in the metropolis, especially those handling dry-goods lines, depend on printed matter for their sales.

The Innocent Bystander

AS a result of the walkout of printers, millions of copies of these catalogues were not printed, or were printed several months late. According to Roger Babson, who is quoted in Mr. Olds' book, "The whole manufacturing programs of hundreds of these firms were held up because they could not get out their catalogues. It is estimated that these firms employ more than 500,000 persons, and indirectly give work to 1,000,000 others. Thus the strike of only a few thousand men in one industry affected 1,500,000 in another line of production. And back of these 1,500,000 are still more men and women whose work and earnings suffered."

Some idea of the economic effect of the present textile strike may be gathered from the story of a smaller textile strike in the spring of 1920. A certain group of cotton mills in the Fall River district were closed for 18 weeks by a strike. In addition to the loss of production and wages, the manufacturers lost a body of skilled workmen they had been building up for years. But the greatest loss was further removed from the mills. Here is how:

The commission house in New York that handles the production of this group of cotton mills employs a large group of salesmen. Each of these salesmen has a string of customers who regularly depend upon the company to supply them with certain classes of material. To keep the sales organization together and the customers contented, the company had to go into the open market to buy the goods that their own mills usually produce. Because of the shortage, which was due largely to this very strike, they had to pay just \$2,000,000 more for the goods than it would have cost them to produce the same material. Another \$2,000,000 wasted needlessly!

Union labor's reply to statements pointing out the excessive

One of the futuristic views of New York that provide an aspect unique among the cities of the world.

The finishing touches to the modern factory—the careful, “hand-made” concrete roof. (Photo courtesy Turner Construction Co.)

cost of strikes is this: “Regardless of the cost, we must strike to protect ourselves. The strike is the only weapon by which the American worker can win increases in wages and maintain his standard of living.”

To this Mr. Olds replies that strikes cost the workers more in wages lost than they gain in increases. The net result is a loss. He specifies:

“Carpenters, through various strike ‘victories,’ got a 65% increase in their rate of wages in 1919, but their actual earnings decreased 3%.

“The coal miners, as a result of the great coal strike and all the maneuverings and politics and negotiations that followed got an increase of 14% in wages. But because of the system that the strike ‘victory’ helped to perpetuate the average skilled miner is getting 50% to 60% less wages than he otherwise would be earning.

“As a result of the clothing strike ‘victories,’ wages were increased from about \$35 a week to \$65, and often more, for 35% less work. But a year later, during what is normally the busiest season of the year, half of all the clothing workers were walking the streets.

“As a result of various strike ‘victories’ in 1919, many classes of textile workers got an aggregate of 22% more wages for a considerably lessened production. But after months of idleness during the latter part of 1920 the same workers were glad to take as much as a 30% reduction of wages to get back to work for even part time.

“In the steel industry, on the other hand, where the strike failed, while wages were voluntarily raised from 114% to 150%—but on the basis of full maintenance of production—during 1920 there was practically no unemployment; the reduction of wages which some of the smaller companies made, due to the demand for reduced prices, were trivial in comparison, and the largest steel companies, up to March, 1921, had not been forced to reduce wages at all.”

It is not necessary to accept all of Mr. Olds’ statements in order to agree with his general argument.

The less tangible evil effects of strikes are no less extensive than the money losses. Strikes, and the spirit that leads to them, produce bitterness between employer and worker, cause labor to be inefficient, and create worry and mental wear and tear throughout industry.

The worry incident to strikes affects great numbers of persons. A man whose business is to supply live chickens to the Kosher butcher shops of New York’s East Side said the other day that the railway strike was ruining his nerves.

“Some of the railroads in the West have declared partial embargoes,” he said. “When I get down to the market in the morning I’ll probably find that the price has gone up five cents a pound because the dealers think the shipper won’t be able to send them the chickens they expect. It will be hard to sell chickens at the higher rate, and the market will come down. Then there will be another strike rumor, and she’ll shoot up again. Trying to follow it and do business is driving me half crazy.”

The inefficiency due to the strike spirit is most flagrant in the building trades. A grand jury which conducted an investigation into the construction industry in Cleveland not long ago reported:

“We should be remiss in our duty did not we point to a lamentable condition which no doubt has injured the very group (labor) which created it as much, if not more so, than the public generally.

“We refer to the present tendency upon the part of mechanics, artisans and laborers of all trades to do less than a full day’s work.

“The testimony adduced before us indicates conclusively that it requires approximately twice as long, with the same number of men, to erect a house today as it did in pre-war times.

“Impartial tests show that it takes twice as many carpenter hours to do carpenter’s work on a building as it did five years ago.

“Bricklayers lay less than half the number of bricks; paper-hangers, painters and plasterers all do less than half the work in the same time that they did five years ago.

“Manufacturing firms which make and sell building materials prove by their records that while wages have gone up 200% in some instances, labor cost has gone up 400%, indicating that their employees are getting double pay for one-half the work, as compared with the period before the war.”

So costs go up, and industry suffers. All this is due to strikes and the spirit of strikes. If we all realized how expensive it is to carry on industrial warfare, would we not devote our energy to stopping it?

A Good Time to Start a Business?

IT is easy to be sagacious in boom times. A large part of American business psychology consists in being anxious to invest when securities are high and to get panicky and wish to sell when values are low. The American is a poor gambler on his country's future—he is apparently disinclined to play long on America during and immediately following depression.

A casual study of the much-discussed business cycles reveals the basic similarity of all economic movements through boom times with high prices, low interest rates and inflation, through deflation with falling prices and heavy capital charges, to the readjustment period with low production costs and low money rates.

Obviously the best time to begin a new enterprise is at that stage of the cycle immediately following the depression—that stage, in other words, which witnesses the first signs of returning health, such as steadying prices, higher bond values and increasing production. The casual study of cycles referred to makes it possible to carry out the maxim: Buy low and sell high. There is neither magic, luck nor a sixth sense in being able to play with the cycles.

The charts on this page reveal the present trend of the cycle as being definitely on the upward path to prosperity. Continued higher security values and continued decrease in the number and liabilities of failures are not unrelated accidents. Making full allowance for the "prosperity talk," and fully discounting future hopes, the fact remains that investments are surer of increasing yields and that the chances of business fatality have been considerably lessened.

The answer to the question, is this a good time to start a business?, becomes almost self-evident. A moment's reflection brings the fact to mind that in spite of the rosy prospects in boom times prices must come down and large profits yield to stringency. The enterprise begun in boom times is soon likely to find itself saddled with inventories, stocks bought at high prices, markdowns and heavy capital charges—a combination of bogies that is liable to spell ruin. Unless all past economic signs fail this is an opportune time to launch an enterprise, always assuming, of course, a sound understanding of one's business and a freedom from "get rich quick" psychology.

What Constitutes the "Spread"?

IN an open letter to Senator Porter J. McCumber, chairman of the Senate Finance Committee, the executive committee of the National Retail Dry Goods Association refutes the sweeping charges that American newspapers were subservient to advertisers and that American merchants were profiteering tremendously at the expense of the people. In making this charge the Senator designated the "spread" between the foreign cost and the retail price of each of the articles of the exhibit as the profit. For example one of the Senator's statements was as follows: "Here is a little watch, silver-backed, I think. I do not know whether it is bought by the gross or by the piece. The foreign cost is \$1.00, and it is retailed in this country for \$9.45. The spread therefore is \$8.45 and the profit of course would be 845%."

But the Dry Goods Association letter points out that to the

foreign cost of any article must be added the cost of foreign buying, inland freight abroad, consular fees, freight and insurance, duty to the United States Government, custom house charges, general overhead, the cost of doing business in this country and Federal and other taxes. The spread between the cost so determined and the price at which the goods are sold represents the true profit.

That the importance of imported merchandise to retail stores lies in quite another direction than "profits" was shown in the brief which the Association submitted to the Senate Finance Committee on January 17, 1922. In that brief it was stated "of the entire membership of the Association a very small proportion only do any direct importing and the total amount of imported commodities, whether directly imported

(Turn to page 1320)

Walkout or Holdup?

Is the rail shopmen's position tenable—or will they put business in the position of saying to the shopmen, the coal miners and the textile workers—"Three strikes—and out!"

THE railway strike presents an interesting opportunity for the study of the use of diplomacy in industrial warfare. All three parties to the strike—railways, unions and Government—devoted their chief attention during the first two weeks of hostilities to jockeying for the diplomatic advantage. They all issued statements, demands, denials, counter-claims, threats

(Washington Evening Star)

Along with other reductions.

and appeals to the public. The relative positions of all three parties changed from day to day, creating an effect upon the public of considerable uncertainty and confusion.

The strike opened quietly, giving alarm to only a few. Shortly after the shop crafts walked out the maintenance-of-way unions announced that they would not strike, and it seemed that Mr. Jewell's men were isolated. Predictions were heard on all sides that peace would come soon. Everyone pitied the poor strikers, and predicted that they would capitulate in a few days. Mr. Jewell apparently felt the uncertainty of his position, and hastened to make it clear that he was ready to discuss peace. The Railway Labor Board, not to be left in the background, also sent out diplomatic feelers intended to lead to an armistice. Only the executives, who felt strong, said little.

This situation lasted only a few days. Reports soon began to come in that trains were late because of the strike. Some of the roads announced the cancellation of trains, and proclaimed freight embargoes. This lent strength to the diplomatic position of the unions, which gave statements to the newspapers showing that the walkout was complete, and attributing the embarrassment of the railroads directly to the strike. Many of the roads attempted to counteract these statements by declaring that the delays were not due to the strike, but would have occurred in any case.

At this point violence began to appear, and the strike seemed less harmless than it had looked at first. Mr. Jewell denied responsibility for violence and warned his men to be careful. The American Federation of Labor began to permit the public to know that it was supporting the strikers. The maintenance men, the clerks and other unions talked strike again. Eight thousand stationary firemen, engineers and oil-

ers announced a walkout. Things began to take on a serious tinge.

This was the signal for the Administration to make itself felt. It would not do for the Government to let it appear that it was not protecting the people. Accordingly President Harding proclaimed officially that the trains would run or Uncle Sam would know the reason why. The Post Office and War departments let it be known that they were ready for all contingencies.

Yet unions, roads nor Government were willing to appear too belligerent. All three wanted to be in the best possible position when the time for a settlement really came. Therefore calls for conferences were issued, private conversations were held and vague hints at terms were passed from one hand to another. One moment things looked hopeful and the next moment things looked black again—all because of the diplomatic jockeying for position.

The confusion of this situation was reflected in the editorial comments of the newspapers. Most editors seemed unable to determine just what the situation was at any particular time, and how seriously the strike should be taken, and accordingly contented themselves with condemning the unions and urging a prompt settlement.

Among the few newspapers that saw a little beneath the surface was the *New York Evening Post*, which pointed out

(Chicago Tribune)

Jeopardizing his lead.

as follows the difference between the situations of the railway shopmen and the maintenance men:

"When railway shop workers and maintenance-of-way men talked strike in the last days of June it was assumed that both classes of employees had a common ground for action. The recent wage cuts were the *casus belli*. Actually the two organizations have separate grievances. For the maintenance men, as the lowest-paid class of railway labor, the wage reductions are a real issue. Measured absolutely, a maximum

weekly wage of \$16 is hardly a living wage. Measured relatively, the reduction in pay for the maintenance men was heavier than for the shop workers with nearly three times as large a wage.

"To the shopmen the real issue is not wage reduction but the defense of their organization against the practice of out-contracting by the railroads, a practice which removed a large number of men out of the protection of the transportation act, both as regards working conditions and pay. It was a real grievance, but not a justification for striking, inasmuch as the Labor Board had declared against the out-contracting practice and had already brought pressure to bear on the railroads, with results which promised an adjustment of the problem in the near future. The shopmen struck against a Labor Board that sided with them on their principal demand. Before the strike broke it was intimated from labor sources that if the out-contracting issue was settled a strike could be averted. Yet today we have the strike of shopmen and as the first result a declaration by the board that the strikers are no

longer under the protection of the board. The strike has intensified the menace against the union which it was intended to avert.

"The maintenance men have been fortunate in the possession of better leadership and greater common sense. Instead of flouting the promise of relief held out by the Labor Board in the form of a possible upward revision of wages, they have accepted that promise as sufficient reason for holding off the strike. That is excellent tactics. Their case for a reconsideration of wage cuts, originally a good case, is now strengthened in the public mind by their refusal to run amuck at the public expense.

"It is not too late for the shop workers to get back to a policy of common sense. If they announce their intention to return to work in the expectation that the Labor Board will do them justice by abrogating the out-contracting evil, the public will overlook the exuberance of a 'runaway' strike. That same announcement a week later will be regarded only as a confession of defeat."

Car Loadings Rise Despite Strike

THE drop in loadings in November and December is a normal phenomenon and is chiefly accounted for by the seasonal let-up in the coal and grain movement. As loadings drop idle cars naturally increase. The accompanying chart shows the idle cars in good order only.

Normally the early months of each year witness a decline in car loadings. The opposite trend in the current year was believed by some to indicate a marked trade revival, but a considerable part of it was due to the stimulated movement of coal in anticipation of the strike. Cars were not only used to move coal, but were also employed in considerable numbers to store it.

With the beginning of the strike on April 1 coal loading dropped sharply and this brought down total loadings. Beginning with the middle of that month, however, total loadings again started upwards, and they have now reached the high point of the year in spite of the loss of coal traffic, indicating that general business has actually improved considerably. The latest report on car loadings did not give separate figures for grain and general merchandise loadings for week ending June 10 and these are not shown.—(N. Y. Evening Post.)

New Air Brake Insures Effective Control

EDGAR E. CLARK, former chairman of the Interstate Commerce Commission, appearing before Examiner Mullin, urged the adoption of the automatic straight air brake, which, he said, has been found safe and effective.

In urging this new brake, Mr. Clark enumerated these defects in the type now used, as evidenced in the records of the commission:

(a) The inability to control heavy trains down heavy grades, without the use of hand brakes.

(b) The inability to obtain emergency pressure during or immediately following a service application. This defect has resulted in accidents due to emergency arising after the service application had been made, and to the fact that the emergency pressure was not for use.

(c) The undesired emergency application of brakes, due to faulty construction and operation of triple valves, again causing many accidents, breaking in two of trains, derailments, injuries to employees and others because of the unexpected shock, pulling out of drawbars, and even the ends

of cars, damage to the lading of cars, including inflammable and explosive articles.

(d) The difficulties encountered in attempting to release the brakes on the rear end of long trains, resulting in the pulling out of drawbars and other damage to cars and lading, and in injuries to employees.

(e) Uneven braking, due to varying piston travel, causing flat and broken wheels, which, in turn, cause derailments and heavy loss.

Mr. Clark showed that the cost of the wheels so destroyed is a very important item in the operating expense of the railroads, but that with the adoption of the automatic straight air brake all of these troubles would be eliminated. With it, any train could be controlled safely and securely on any grade and under any conditions. With it emergency pressure would be available at all times. It would also equalize the braking power throughout the train regardless of uneven piston travel.

"There's Business in Brazil"

Of all our South American neighbors the United States of Brazil offers perhaps the best opportunity for manufacturers desiring export outlets.

BRAZIL, according to a report of the United States Department of Commerce, is "a field of great potential wealth, the exploration of which has scarcely more than begun, and which offers in the future unmeasured opportunities for trade in both directions. . . . A number of elements have combined to create a favorable market in Brazil for goods from the United States and the country offers a more promising immediate opportunity for various lines of our export trade than any other in South America."

Surely American industry, which needs to cultivate its export markets assiduously if it is to reach the high prosperity of which it is capable, will find it worth while to pay attention to such an opportunity.

Brazil as a commercial nation will be brought to the attention of the world by an international exposition, commemorative of the one hundredth year of Brazilian independence, to be opened in Rio de Janeiro on September 7. The products of many nations will be exhibited, and the Congress of the United States has appropriated \$1,000,000 to pay the expenses of American participation. Therefore a review of the trade possibilities of Brazil is timely now.

In spite of the fact that the exploration of Brazil's wealth has hardly begun, that country has been for some time one of the leading nations with which the United States has traded. In 1921 we shipped goods valued at \$128,746,345 to Brazil. Our imports during the same year amounted to a slightly larger sum: \$147,520,940.

Between 40% and 50% of Brazil's total imports come from the United States. In 1919 we sent her 48% of her imports, and in 1920 the figure was 42.1%.

Brazil's Chief Products

THE chief wealth of Brazil lies at present in two products—coffee and rubber, shipments of which make the larger part of her exports to us and to the rest of the world. Besides these, Brazilian products of greater or less importance are cotton, cacao, sugar, yerba maté (Paraguayan tea), tobacco, nuts, hides and skins, gold, manganese ore, precious stones and carnauba wax. Mahogany, ebony and a variety of other hardwoods are scattered through the forests and might be profitably exported, but at present labor is lacking, and the cost of getting out these products is prohibitive. Fiber plants, fruits and grain are other products which might be developed if the energies of the people of Brazil were not otherwise directed. The nation also possesses deposits of iron and coal which some day may be of importance.

The State of Sao Paulo produces a large part of the world's supply of coffee. Two million of the 4,500,000 acres under coffee in the whole country, and 685,000,000 of the 1,320,000,000 trees, are in this State.

The rubber forests of Brazil, according to a Brazilian authority, cover an area of 500,000 square miles. This is half of the entire rubber regions of South America. Until the development of cultivated rubber fields in the Far East, especially in Ceylon, Brazil was the foremost rubber-producing nation of the world. The Ceylon rubber, although not equal in quality to the *Para Fina* of Brazil, serves most purposes, and is seriously damaging the Brazilian trade. The price of the wild Brazilian rubber has been kept up by the heavy import duties on supplies going to the rubber district, the difficulty of transportation, trouble with the rubber laborers and similar difficulties. The Brazilian government is endeavoring to improve the situation.

The United States is Brazil's best customer for her coffee and rubber. In acknowledgement of this fact, Brazil allows preferential tariff treatment to many American commodities which she imports.

Brazil's Principal Imports

THE principal items which the United States sends to Brazil are machinery, which is now Brazil's chief import; flour, wheat and meal, in which Argentina is our chief competitor; coal, shipments of which in the past have also come in considerable quantities from Great Britain; railway materials; electrical machinery, in which Germany used to be our chief competitor; iron and steel products, in which trade Great Britain still shares and which was formerly enjoyed to a large extent by Germany; and petroleum products, in which trade we predominate. The proportionate shares of the United States and our chief competitors in the Brazilian import trade are shown in this table:

	1913	1919	1920
United States.....	15.7%	48. %	42.1%
Great Britain.....	24.5%	16.1 %	21.2%
Germany	17.5%	0.21%	5.0%
France	9.8%	3.79%	5.6%

The war, of course, has given us a tremendous advantage over France and Germany, and has also improved our position in regard to British competition.

Machinery is the Brazilian import which seems at present to hold out the greatest promise to American exporters. In value this item is the leading import of the country, and its value is rapidly increasing. Brazil's machinery imports jumped

from 66,127,000 milreis in the first six months of 1920 to 151,134,000 milreis in the same period of 1921. (The milreis was quoted in New York at about 14 cents in the early part of July, 1922.)

This increase in machinery imports is a symptom of the growth of Brazil's manufacturing industries. The government has fostered these

A New Plan for Charting Production

HOW can an individual, *without* the use of collected data and statistics depict business conditions in graphic form? (This, by the way, is not taken from the Edison questionnaire.) The average answer would be that it cannot be done. Yet it can and is being done and in no less a city than Cleveland.

The data compiled by statisticians are, in a measure, a gauge of the business transacted within the district to which the facts apply. The difficulty in statistical work, however, lies in the proper evaluation of one group of facts with relation to the whole group of facts. Further, the conclusions drawn from such correlated data represent more or less the personal judgment of the individual compiling the data.

A better means for presenting business conditions within a district is that used by the large central stations supplying electricity to such communities.

"It is well known among experienced engineers and manu-

plant may be accurately measured by the kilowatt hours of electricity used.

In Cleveland, a large industrial center where electricity is the main factor in driving the wheels of industry, the amount of finished products, during any period of time, can be judged very accurately by comparing the total amount of electricity generated by the central station with that generated in some other period.

It therefore follows that a study of the "load curves" of the illuminating company supplying most of the power used in Cleveland's factories and industrial activities may be of interest as representing the total kilowatt hour output from its power plants, and as indicating the trend of business in the near future.

Electricity, as compared with other forms of data, is a most trustworthy guide in determining business conditions. Take, for instance, the bank. The banker takes the dollar for

An example of the practical use to be made of charts. To a company selling electric current, power generated is a direct indication of production in the territory served. Even the best report with tabular data is still incomplete and is not thoroughly comprehensible unless accompanied by such charts clearly presenting the trend.

facturers," says G. E. Miller, writing in *Trade Winds*, "that in a shop or manufacturing plant driven by electric power, the volume of finished product may be very accurately measured by the amount of electricity consumed in its production. For instance, the experienced manager of a steel mill can translate the kilowatt hours of electricity used in his mill over a definite period of time, into tons of steel rolled for the same period, with surprising accuracy. He is able to do this because the electricity used represents work done in making the finished product."

Wherever electricity is used, therefore, and when data are available over a sufficient period of time, the output of a

his unit of measurement in gauging business conditions. But this can never be an accurate gauge since "the bank clearings of a particular day or week do not measure fairly the productive capacity of industry for that period, as obviously they may reflect business done by selling goods from stock when the plant producing the goods is completely shut down. Many other factors enter which make the dollar an untrustworthy unit of measure with which to gauge the industrial output of the community for any particular period."

On the other hand, kilowatt hours measure the work done today, and consequently goods produced today. "Electricity

(Turn to page 1319)

The New Styles in Letterature

"**B**USINESS men today are getting entirely too clever for me," said Old Man Jarvis. "I can't keep up with them. In my day a manufacturer was just a manufacturer, and he left artistry to the artists and science to the scientists, contenting himself with making his product and selling as much of it as he could at the highest price he could get. But today a business man is also a psychologist, an economist and a literary artist; and if he can't be all three himself he hires others who can supply his scientific and artistic deficiencies.

"It's beginning to get on my nerves. I don't like to think I'm a back number, but I can't stand the pace that you youngsters are leading. I'm doing my best. I have a psychologist handling my advertising for me, and when he says to me, 'Mr. Jarvis, the psychology of our buying public demands that we start a campaign in every leading national magazine of the country to overcome the economy-complex instilled in the minds of the people by reaction from the post-war exuberance,' I try, as often as possible, to tell him to go ahead; and when the time comes to pay the bill I congratulate myself on being a modern, psychological business man. Likewise, I subscribe to an economic service that sends me charts looking like the cross sections of the Rocky Mountains in the school geographies, labeled: 'Fluctuations in the price of white lead fence paint during the panics of 1789-90 and 1883, correlated with a graphic representation of the production of wire nails in the United States from the close of the Civil War to the present date. On the basis of this illuminating and instructive chart we advise our clients to buy all the suburban real estate they can lay their hands on.' I study all this material with the utmost care, glad to be among these progressive business men who call the science of economics to their aid.

"But the literary artistry of present-day business is too much for me. I can stand the psychology and the science, but not the literature. The other day I got the following letter from a firm that used to sell me goods.

'Universal Manufacturing Company

"Buffalo, N. Y., July 1, 1922.

"Dear Sir:

"Jim Smith stood in front of the post office, wrestling with his chronic dyspepsia, just as the noon whistles sounded.

"'Twelve o'clock, eh?' he said, half to himself and half to an acquaintance. 'Well, I'm going home to dinner. If dinner ain't ready I'm going to raise hell; and if it is ready I ain't going to eat a bite.'

"Smith refused to be pleased any way you look at it.

"Fortunately for us, however, our customers are nothing like Jim Smith. Take your own case, for example? You have not been dealing with us for a long time, but—"

"The letter went on like that for a page and a half. I read it with tremendous interest, and was glad to see that there was no line at the end reading 'To be continued.' I wouldn't have been able to eat or sleep until the next instalment. It was a novelette.

"Frequently I am surprised by outbursts of literary skill from the most unexpected quarters. Not long ago a young fellow called on and tried to interest me in a line of goods such as we use pretty regularly. He wasn't such a bright young man. Indeed, I noticed that from time to time a grammatical error would creep into his selling talk. But the stuff he showed me seemed pretty fair, and I laid aside his card, intending to get in touch with him if we should ever have trouble with our present source of supply in his line. After his visit I occasionally received catalogues and notices of price revisions from his firm, and I put them away in my

scientific filing system, without which no modern business office is complete.

All of a sudden I got a letter over the salesman's signature that opened with a lot of question marks:

Martian Aero Service Company

"Philadelphia, July 7, 1922.

"Gentlemen:

"? ? ? ?

"? ? ? ? ? ? ? ? ? ?

"That's the way I feel about your account.

"I've been angling for your business—exerting every possible effort to interest you in our lines—posting you at frequent intervals on new things and especially active items, that I felt sure should interest you.

"But to no avail.

"And on top of that I see, too, that the letter I wrote you the other day after Mr. ——— had grilled me on my inability to elicit as much as a reply from you to the many, many letters I have sent you, also remains unanswered.

"Why? That's what gets me. Am I not entitled at least to the courtesy of a reply from you?

"Let's just change places for a moment—if you knew and were sure that you were able to serve me as well, or probably a little better, than the next fellow—

"If you know that the merchandise you were offering was absolutely right in price—

"If you knew that I used your merchandise, and that you were in a position to give me immediate attention and service at all times, wouldn't you feel the same about it as I do?

"Well, then, listen. What is it that prevents our getting together? Come right out from the shoulder. Tell me candidly and outspokenly just what's wrong. Are you dissatisfied with the manner in which we have taken care of your wants placed with us in the past, or is it simply a case of poor salesmanship on my own part?

"That's not asking much, is it? What's wrong then?

"May I hear from you by return mail via enclosed stamped envelope? Write on back of this letterhead if it's more convenient.

"Yours for business, Jim Brown."

"This sudden transformation of the ungrammatical salesman into an Arthur Brisbane was all the more surprising to me because his letter didn't exactly seem to apply to my case. The sentence asking me if I was dissatisfied with the manner in which he had taken care of me in the past was especially puzzling, because I had never bought anything from him. I continued to puzzle and to admire until one day I saw a familiar-looking row of question marks underneath the letterhead of another firm that was angling for my business. Reading ahead with interest, I saw that this firm had sent me an exact duplicate of the literary outburst of my ungrammatical salesman.

"That made it all clear. I perceived that the modern business man, in order to be thoroughly modern, not only must buy psychological service from the expert psychologists, and economic service from the expert economists, but letter-writing service from the expert literateurs. My ordinary, simple 'Yours-at-hand-and-contents-noted' letters which I had been dictating to my stenographer ever since the typewriter was invented were all wrong. I would have to buy a book of up-to-date, smoothly written, unusual, snappy and entrancing model letters, and base my correspondence on that.

"But I'll be hanged if I will. I'll keep up with the times in everything but that. I'll write my own letters in old-fashioned, brief, understandable business English, and whenever a work of literary art comes to me on the letterhead of a business contemporary I'll mail it to my friend the editor of 'The Literary Review,' to whom it should have been sent (with stamped and self-addressed envelope) in the first place."

Uniform Traffic Signals Coming

THE day is not far off when red, green and yellow, when used as traffic signals, will each have its distinctive meaning, and this meaning will be uniform all over the country, according to the decisions reached at the first fully representative conference ever held on the subject in this country. When that day arrives the annual toll of deaths and serious injuries resulting from traffic accidents will be reduced by the elimination of accidents caused by the confusion or misunderstanding of signals. This conference on the standardization of colors for traffic signals was recently held in New York under the auspices of the American Engineering Standards Committee. There were present representatives of practically all of the big national engineering societies, safety associations, electric and steam railway interests, automobile dealers, manufacturers and users associations, police and traffic departments, insurance companies, and several departments of the federal government.

The conference agreed unanimously "that there should be national uniformity in the use of colors for signals," and that the detailed technical work involved in bringing about such uniformity should be carried out by a thoroughly representative sectional committee under the auspices and procedure of the American Engineering Standards Committee. Included in the scope of the work as defined were the following:

The use of colored lights on all highway vehicles; their use on all signals along highways and at curves, both permanent and temporary; their use for highway crossing signals for steam and electric railways; a coordinated relation of color, form, position and number of signals; a coordinated

relation to systems of flashing, moving or other similar lights; colors for non-luminous as distinguished from luminous signals; recommendations on the use of colors for emergency exit signals; methods of specifying or defining colors for signals purposes; any other closely related matters which, in the opinion of the sectional committee, form a part of the subject to be considered.

It is very easy to place the entire responsibility for automobile accidents on the automobile driver while, as a matter of fact, the responsibility for conditions which exist rests not merely on the motorist, but also on the pedestrian and upon the steam and electric railways.

Pedestrians often cause automobile accidents by ignoring traffic rules. Watchmen are not always at grade crossings when the signs say they should be there; and grade crossing gates are, at times, down for considerable periods when trains are not going through. National uniformity in colors for traffic signals is extremely desirable, but if major changes are to be made—as, for example, a change in the color of tail lights for automobiles—it would take at least two years to get such changes into operation because legislation would be required in most states.

On the motion of Dr. M. G. Lloyd, of the U. S. Bureau of Standards, a resolution was adopted declaring it to be the sense of the conference that any sectional committee of the E. S. C. which takes up the standardization of colors for signals should endeavor to coordinate such standardization with existing standards for traffic purposes, such as those used in water and aerial navigation and on steam and electric railways.

WITH THE FINANCIER

The Situation in Europe

CONSIDERABLE attention is being paid in the financial markets to the European situation. Foreign exchange and the prices of the bonds of certain European countries, especially France and Belgium, showed weakness as a result of discouraging news from the conference at The Hague and from Central Europe. Speculators for the decline took advantage of the unfavorable reports, and drove prices in these markets temporarily lower than the news really warranted.

The chief reason for the decline in French and Belgium bonds was the talk of a moratorium on German reparations. The reparations situation is enveloped in uncertainty, but many observers think that the outcome will not be entirely unfavorable. A reduction of the payments that Germany is required to make will certainly not be favorable to France, but it may have a beneficial effect on the international financial situation taken as a whole. The Reparations Commission, apparently with the consent of France, has already agreed to reduce the July payment by 36%, and it is hoped that France may permit further concessions on the ground that it would be better to collect less money than she expected now than to bring about a political and economic upheaval in Germany. It is quite possible that the present crisis may result in an arrangement which will make possible the calling of another meeting of bankers to consider a loan for Germany's benefit.

Low Marks and Markdowns

THIS hope did not prevent the German mark from tumbling lower than ever before. The issuance of paper money in Germany goes merrily on, in spite of strikes, assassinations and threats of revolution that interrupt the functions of every economic agency of the country except the government printing presses.

In this connection a reported action of the Russian Soviet Government is interesting. The Soviets, it is said, have reduced the number of rubles in circulation by eliminating the last four ciphers from the outstanding ruble notes. In other words, a note for 10,000 rubles is now a note for only one ruble, and the 75,000,000,000 rubles formerly in existence have been reduced to 7,500,000,000. The *New York Times* remarks that "this scaling down is nothing other than repudiation and it emphasizes the fact that the Soviet Government is in a precarious situation."

Hot Weather Dulls Stock Market

THE stock market is afflicted by hot-weather dullness. Highly speculative stocks are rising and falling as the result of professional operations, and the list as a whole is holding up well. Observers say that the situation shows strength.

"Strong financial interests, which have been applying severe analytical tests to the market, are greatly impressed with its resiliency," writes S. S. Fontaine. "They do not hesitate to express the opinion that, with the satisfactory completion of the harvests, particularly if an ample corn crop is garnered, we shall have a notable movement in securities during the Fall and early Winter. They admit that the reasonable assurance of these desirable developments may lead to an anticipatory movement during the summer."

"It is significant that some of the more farsighted market leaders are planning to spend the greater part of the vacation period in closer touch with the Stock Exchange than has been their practice in recent years."

Bonds Show Good Health

IN spite of the weakness in certain foreign bond issues the bond market as a whole is in extremely good shape. The *New York World* points out that in response to the reinvestment demand created by distribution of July interest and dividends the major portion of the bond market early in the month reached the highest average level of the year and the highest on the recovery from 1920 and 1921 low points. Liberty 4½% issues made new high records, with the exception only of the second converted bond of the first loan. High grade railroad bonds were in strong demand and limited supply; standard rail, public utility and industrial issues were well absorbed; and the cheaper bonds also were inclined to higher levels. The higher grade of securities made the greatest gains, because funds for reinvestment naturally flow into such channels.

Underwriters of new bond issues were encouraged to bring out large volumes of securities, and they had little difficulty in getting rid of their wares at good prices. State and municipal bonds continued to be sold in considerable

Wholesale prices from 1860 to 1922, the prices of 10 rail bonds, and 60 rail stocks (crosshatch bars indicate years of depression).—(L. P. Ayres, Cleveland Trust Co.)

quantities. Compilation of the records for June showed that an aggregate par value of \$154,273,633 permanent State and municipal bonds were successfully marketed in that month. This brings the total for the year up to \$713,070,097, according to a table compiled by the *Daily Bond Buyer*. If as large a volume of this kind of financing is done during the remaining six months of the year the record total of 1921 will be exceeded. Advance reports, however, do not indicate that borrowing will be maintained to the same extent during the summer or even after the elections in the fall. If these reports are correct industrial and railroad corporations will be relieved of a part of this competition in the investment market.

Belgium a Good Cotton Market

IT is believed that a sustained demand for American cotton in Belgium is practically assured as a result of the improved condition of the cotton textile industry in that country. During the first quarter of 1922 the value of imports of American manufactured products decreased 50%, but imports of American automobiles, starch, paints, paper and hardware showed noticeable increases.

Unemployment Period Nearly Ended

THAT the period of labor liquidation is rapidly drawing to a close is indicated by the chart shown below. Although wage reductions are still in progress throughout the country they are being counterbalanced in many sections by wage advances. Employment statistics throughout the country indicate that the period of unemployment is practically closed. While a surplus of unskilled labor is found in Portland and Seattle, Washington; St. Paul, Minnesota; and Albany, N. Y., nearly all localities report increasing employment in practically all lines and many even report shortages of workers.

It is believed by some students of the labor problem that the curtailment of immigration is responsible for the labor shortage. If this is the case it will probably result in a relatively higher wage for unskilled labor, which will mean an increased cost of production for those industries in which common unskilled labor is an important item.

Million and a Quarter Men Idle

ACCORDING to the *Industrial News Survey* of the National Industrial Conference Board, nearly 1,240,000 persons are now idle because of strikes in various industries. It is estimated that it would require the labor of 100 men working for over 30 years of 300 week days each to make up for the time lost for each week of idleness. Moreover, it must be remembered that this loss includes only those who have voluntarily left their employment. If the strikes continue a large number of persons engaged in secondary or allied industries dependent on the major industries will be forced into involuntary unemployment.

Labor's Food Bill

A REVISION of the index numbers showing changes in the level of wholesale prices has recently been made by the Bureau of Labor Statistics. This revision consists in regrouping the commodities, the addition of a number of new articles, and the substitution of the 1919 census data for

weighting purposes instead of the 1909 census data previously employed. The index figures, as thus revised, show for "all commodities" an average of 148 for May, 1922, as against 143 for April, or a rise of five points in a single month.

However, this index of wholesale commodity prices does not furnish a basis for determining wages, since the worker does not buy at wholesale but at retail. And in the case of rent and fuel, particularly, there has been no appreciable drop in price. In spite of the fact that the dollar purchases more than in 1920, its purchasing power is still below that of 1914, consequently wages today are, in reality, only slightly higher than they were at that time.

R. R. Wage Bill Reduced

A RECENT report of the Interstate Commerce Commission states that the railroads of the United States in April of this year paid \$203,413,071 in total compensation to 1,578,133 employees. This is at the rate of \$128.89 to each employee. While this was an increase of 7,975, or one-half of 1%, over the number of employees reported for the preceding month, the total wage bill was decreased, compared with the preceding month, by \$13,291,337,—or 6.1%, owing to a reduction in the number of higher-paid employees.

Labor Banks and Newspapers

TWO of the most important developments during recent years among labor organizations have been the formation of labor banks and the inauguration of press associations for the service of labor newspapers. The fact that labor organizations need sound financial backing during a strike is obvious. Many labor leaders claim that one of the reasons why labor has lost in many of its struggles during past years appears to have been due to the fact that organized financing and a well-developed newspaper service have been almost wholly lacking. But labor unions are at last realizing that numerical strength alone does not always mean power, and instead of dwelling upon the necessity of securing new members they are bending every effort to the reorganization of their resources.

Chart compiled from figures of Bureau of Labor Statistics, showing percentage increase or decrease in employment and wages, compared with same months of year preceding. Aggregate numbers employed and wages paid in identical establishments are used in compilation. Black areas are periods of labor prosperity when per capita wages were increasing. Shaded area, now developing, indicates extent to which tide is swinging away from labor.—(United Business Service.)

IN THE MANAGER'S OFFICE

Industrial Production Principles

SAMUEL CROWTHER, in *Factory*, describes four principles of production which Henry Ford regards as basic. These principles, as applied in the Ford plants, are: (1) No process, no method, is ever considered as having been perfected. It is considered as in use only until a better method is devised. Therefore the attention of everyone is fixed upon doing the thing better and there is never an opposition to change. A good deal of the difficulty which attends the introduction of a new method in the average plant is that which is due to the opposition of those who want to let well enough alone;

(2) The foreman in charge of a particular operation does not bother with costs. He does not know the costs. His department gets its score from the number of pieces produced per day divided by the number of man hours worked. His rating depends upon decreasing the human labor content of the pieces produced by his department. Therefore he is eager for every improvement that will increase output;

(3) The department heads and foremen are not bothered with cost sheets for the elementary reason that most of the costs are beyond their control. A department head cannot control wages or the cost of material or administrative overhead. Therefore the position is taken that he should not be bothered with figures he cannot alter. His mind should not be diverted from what he can control to what he cannot control. He can control the unproductive ratio in his department, and he can control the output per man, and these are the figures that show in his score;

(4) In the accounting no charge is made for interest upon the investment. This is a fundamental point in Mr. Ford's theory of business. The whole plant is considered merely as a productive tool and it is worth what it returns in the way of production. The process is not complicated by considering what might have happened had the money, instead of being put into a productive tool, been put into 6% securities. That is to say, interest upon the investment is not taken into consideration anywhere in the accounting of the company.

Making a Sales Budget

USING the sales quota as a basis for the plant budget is described by A. J. Lutterbach in *Business*. The sales budget provides a plan of general action toward a specific goal, sets a selling pace for the men in the field and establishes a guide for executive control.

The first step toward the establishment of a sales budget for the year is to determine the objective. Some of the factors to be considered are general business conditions, past, present and anticipated; last year's volume and the ease or difficulty with which it was attained; and the attitude of the buying public. After analyzing these and other factors the desired percentage of increase in sales is determined. The next step is to allocate the increase to the various divisions and territories.

Where more than one commodity is produced a ratio of increase is determined for each product. This ratio is allotted to each department and becomes the departmental quota. The new quotas are based to a large extent on past performance as revealed by the classified record of sales.

Having established and distributed a quota to the goods to be sold the next consideration is the quotas of the men who

will sell these goods. After careful analysis individual quotas are set up and the district managers advised of the amount of sales expected from each of their men during the ensuing year. A salesman is required to sell a certain minimum number of units; that minimum is his "commission quota." When he has sold that number he begins to draw commissions on further sales of the product. When a district falls behind, or when a commodity slumps in sales, an investigation follows and measures are taken to insure the attainment of the quota.

To sell goods the company must first make goods and the factory determines how much to make from the sales budget. To finance the operations, meet expenses, procure raw material and secure money for extending manufacturing facilities, the financial department must know the anticipated load. This information is obtained from the sales budget. For each department in the plant the budget is divided and allotted just as the selling quota was allotted, to the individual commodities.

For computing the advertising budget the basis is again the selling quota. Every article carries a fixed advertising charge. This charge, multiplied by the number of units to be sold, establishes the total to be spent for advertising.

Trade Acceptances and Production

THE relation of the use of trade acceptances to the problems of the production department may seem remote but in reality this method of collection has advantages which accrue to every operating department, especially in industries of a seasonal nature. Arthur H. Little, in *Business*, outlines the experience of the tire industry which, to a large extent, utilizes the trade acceptance to stimulate production and sales in the dull months. Some of the benefits derived are:

(1) For the smaller companies the trade acceptance has made available as operating capital hundreds of thousands of dollars that otherwise would have lain in the hands of customers;

(2) By facilitating sales well in advance of the seasonal demand, the trade acceptance has made it possible for the factories to keep operating in the dull season at a volume well above the minimum which would compel increases in price;

(3) By stimulating the movement of goods in slack seasons, the trade acceptance has disposed of output that otherwise would have piled up in warehouse storage and simultaneously has prevented the confusion and congestion resulting from a rush of shipments at the beginning of the peak season;

(4) By reducing to the terms of a written understanding the relationship between seller and buyer, the trade acceptance tends to safeguard collections; and by simplifying for the manufacturer the work of collections and for the buyer the procedure of selling, it facilitates the settlement of accounts;

(5) By systematizing his buying, the trade acceptance serves the buyer; it enables him to prepare in the dull season for the demand of the peak and to fill out his stock with goods for which he can pay as he sells them.

Organization Charts

EDITIONAL comment in *Industrial Management* attributes part of the general misconception of organization to the organization chart fad. Organization charts are helpful or dangerous, depending on the use to which they are put. Such charts help to reveal the shortcomings in the existing organization and to clarify the relationships between individuals,

departments and functions. In so doing they help managers to understand and handle their organizations. But the present tendency is to recognize the chart as the important thing, the organization itself secondary.

The trouble does not come from drawing or having a map of the existing organization. The trouble with the organization chart lies in the attitude of mind regarding the conception of it as a finality. Frequently future growth is planned too strictly on the basis of the existing structure. Healthy growth almost invariably means continual and sometimes radical structural changes. When an organization and its future development are rigidly mapped on paper, there is a tendency to regard it as a fixed and final plan to stick to it long after the profitable and expedient time.

Most organization charts do not provide for a crisis requiring contraction. The organization is made flexible only in the direction of growth. Flexibility and adaptability are two of the most necessary qualities for the successful executive, and in charting a plan of organization the idea of finality must be dispelled and provision made for either expansion or retraction, as conditions warrant.

A Material Control System

WHEN capital is in the form of cash it is carefully protected, its receipt and disbursement safeguarded and its custodians held to a strict accounting, but once this capital is converted into materials there is a tendency to become lax and to tolerate practices that are wasteful, inefficient and needlessly expensive. The summary given below of advantages of a material control system is taken from a paper by Arthur Lazarus, of the Chamber of Commerce of the United States.

In the first place, a stores control system should aid in keeping the investment in materials and supplies to a minimum consistent with efficient operation. The supply of specific commodities on hand is largely regulated by conditions of purchase, production and demand. An attempt should be made to avoid a needless variety or a surplus of stock by a study of standard sizes and varieties. The selection of odd sizes and kinds frequently rests on the judgment of an individual rather than upon sound industrial practice. An effi-

cient material system will tend to eliminate distinctions that are not differences and to reduce the inventory to a minimum.

The second requirement of an adequate stores system is to supply men and machines with material in the manner, at the time, and in the amount desired. The investment in materials must be kept low, but not so low as to interfere with production. Parts must not only be physically available in the storeroom, but must converge to the point desired in production at the proper time. An undue accumulation of material in the course of production will seriously interrupt the flow of work.

The third service of the stores control system is a proper conserving of the material investment. This involves checking incoming material

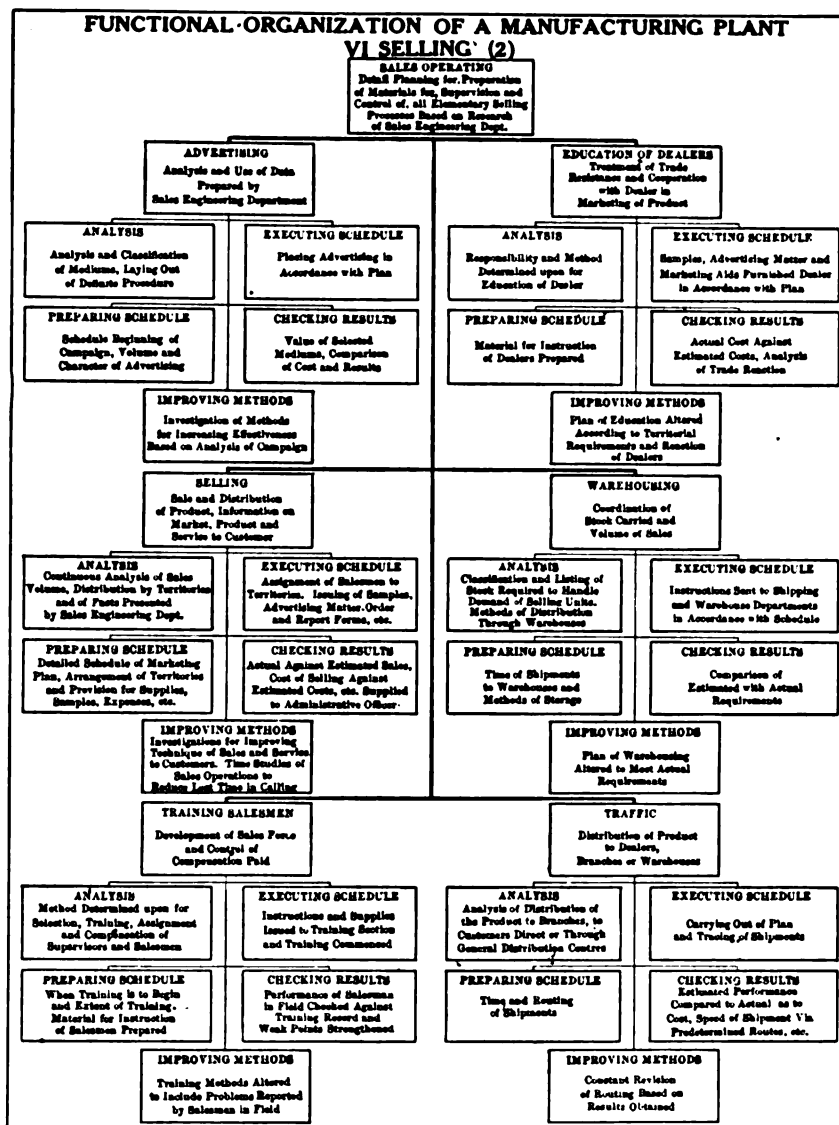

for amounts, quality and condition, placing material where it can be readily found and safeguarding stores against accident and theft.

A fourth advantage arises from the use of the perpetual inventory, frequently checked by actual tests of quantities on hand, which makes unnecessary the expensive, burdensome and inaccurate annual physical inventory, with its general disorganization of the general routine and the shutting down of the plant.

Fifth, a stores control system is an essential part of accurate accounting for material, affording a comparison of actual material receipts with purchase requisitions and a class of dependable information making possible an accurate allocation of the actual cost of material to the proper departments, jobs or processes.

Again, a well-planned stores system will economize storage space. This is of extreme importance to businesses that are expanding and must utilize all available room. The remaining advantages are that records prepared prove invaluable in case of fire loss and provide against the accumulation of obsolescent material.

To a large degree the success of the stores control system depends on the cooperation of foremen and workmen. The control of material does not end with the storeroom or its records; it is a factory problem requiring the hearty cooperation of all the operating departments, and consequently should have the close attention of the directing executive.

Functions of a Typical Industrial Plant

This chart is sixth in a series based to a large extent on lectures given at the Bureau of Personnel Administration by Warren D. Bruner.

EXPORT • IMPORT

Imports to Beat Tariff

THE anticipation of a high tariff appears to have had a remarkable effect upon the importation of various articles on which it is expected a high duty will be levied. According to a recent statement of the Collector of the Customs at New York, the fiscal year ended June 30 has been a banner year in the history of the Customs Department. The receipts are said to have exceeded all previous records.

The actual total for the year ended June 30, 1922, was \$229,548,244 as against \$229,325,365 last year. Compared with last year it showed the following result:

	1921	1922
Duties collected on mdse.	\$205,863,858.81	\$223,662,911.20
Misc. receipts	5,949,890.75	3,995,367.08
Total	\$211,813,749.56	\$227,658,278.37

The principal imports were raw materials for use in manufacture, foodstuffs, fabricated products for use in manufacture and goods ready for the ultimate consumer. The following table shows the duties collected on merchandise imported into this country during the years of 1920, 1921 and 1922:

Duties Collected

	1920	1921
July	\$ 21,468,214.25	\$ 13,443,166.86
August	18,392,047.35	15,237,808.03
September	16,140,523.89	15,203,273.17
October	16,845,472.10	15,657,372.60
November	15,335,704.46	17,078,066.41
December	12,190,678.56	16,799,062.74
	1921	1922
January	\$ 12,265,070.19	\$ 19,322,717.46
February	14,154,348.68	21,620,779.84
March	18,615,006.10	24,650,402.81
April	26,838,089.11	20,639,379.75
May	17,221,669.64	20,909,658.41
June	16,397,034.42	20,101,223.21
Total	\$205,863,858.81	\$223,662,911.29

Automotive

THE smaller export organization, because of its more intimate relation with the foreign market, actually accomplishes more, in proportion to its expense than large, cumbersome organizations. The automotive industry has found this out through its experience in the last two years. Although the records established in 1920 have not been equaled in 1921 the basic strength of the industry is reflected in the increase of both production and exports in 1921, compared with 1913.

It is reported that there are great possibilities for the use of tractors in India. Some of the provincial governments are demonstrating the various uses of tractors to farmers, large tracts of land frequently being plowed free of cost. Several makes of American tractors are now in use in India and are said to be proving quite satisfactory.

Electrical

TELEPHONE and telegraph equipment will be the principal material to be purchased with the £8,000,000 which has recently been placed at the disposal of the Postmaster General of the Treasury Department of the Federal Commonwealth Government. The American trade commissioner at Melbourne is preparing to forward to the Bureau of Foreign and Domestic Commerce all tenders and proposals for construction work in connection with the expenditure of this money, notice of which tenders will be distributed by the Electrical Equipment Division through the various district and cooperative offices of the bureau.

Leather

THE United States export figures for May, 1922, show an increased demand for American-made leather boots and shoes, the exports during the month being 515,373 pairs. The total number of pairs exported represent an increase of 20.1% over the average for the preceding four months.

The quantity of leather belting exported from the United States to various foreign countries during May, 1922, was 79.5% greater than that exported during May, 1921. The most pronounced increases occurred in shipments to Canada, Cuba, British India, China, and Argentina.

Iron and Steel

ALTHOUGH the market for American iron and steel products in Rumania was comparatively small before the war, owing to the preference for German and Austrian metallurgical products, German iron and steel exports to Rumania within the last few weeks have shown a considerable falling off. At the present time it is estimated that Greater Rumania needs some 650,000 tons of iron and steel products, most of which must be imported. The products and articles chiefly

The balance of foreign trade in millions of dollars, 1912-1922.
—(Magazine of Wall Street.)

imported are pig iron, iron in bars and sheets, construction iron, tank steel, soft steel, corrugated iron sheets, tin plate, galvanized iron sheets, iron pipe, wire rope, rolled iron, rails and various kinds of machinery and tools.

Lumber

THE importation of oversea timber through Hamburg during the past year has been favorably influenced by a number of factors, especially by the demand on the part of manufacture, the fall in ocean freight rates, and the development of Hamburg's shipping connections.

The demand for American hardwoods in the Scandinavian markets has increased considerably during the past two months. Sawn oak forms the principal item in importation of American hardwoods, and as it is in this particular product that German competition has been most severely felt, the gradual rise in German prices and the growing inferiority of the quality of their products has enhanced the chances for American exporters. Late shipments from the United States, although not large, show a decided increase.

ADVERTISING

Visualized Advertisements

MANY rules have been prescribed for securing results with hand-lettered copy. As a means for securing attention it has been used by all classes of advertisers. In their search for the unusual they have ranged from precise, widely spaced lettering to flowing script styles that were often the last word in smartness—and illegibility. Every effort was made to incorporate charm, character and pictorial values that would help impress the product upon the mind of the reader of the advertisement. And in many cases by choosing a type of lettering the general character of which was expressive of the product, advertisers were able to secure the elusive quality of atmosphere and achieve a certain distinctive appearance that made their advertisements stand out from others.

The lettering "tells the story" in these examples. Lettering can be made to fashion ideas and impress the quality of the articles advertised, as well as to act as a trade-mark.

But the examples shown herewith represent a still more effective method of putting across the message. In these advertisements the distinguishing characteristic of the product is expressed or pictured in each letter of the name or caption. The outline of the letters forming the word "Disston," for example, visualizes the product more compellingly than a page of copy or an elaborate illustration. It not only expresses the strength necessary in an advertisement of machinery or tools, but it typifies the product itself. Similarly, the words "Keen Kutter," by their formation and arrangement, suggest knifelike sharpness and efficient workmanship.

Not only the product itself but the office it performs, or the end achieved, through its use, may be similarly expressed. The suggestion of intense heat is adequately conveyed in the outlines of the "Sunbeam" advertisement and the idea of refrigeration is expressed by the word "Polar."

A glance at one of the letters of the words "Parker Vises"

is sufficient to acquaint anyone with the product advertised; moreover, the rugged outline serves the twofold purpose of suggesting solidity and dependability.

Of just the opposite character is the caption "Eversharp Hours." The clean-cut lines of script emphasize the desirability of legible characters, make us desire to possess the instrument with which such precise lines were written.

"Signlite" and "Radio" suggest, respectively, electric signs and the wireless, while the somewhat intricate make-up of "Glolog" radiates comfort. Even in plain black and white it carries with it the suggestion of warmth. Another advantage of this form of lettering is its brevity. Since the expressive outline is as a rule used only in the name of the product or in the trade name, there can be no long, heavy lines of type to tire the eye; the unique outline of the letters stands out the more clearly because of the breathing space around it and of the contrast offered by the plain type on all sides of it. In thus adhering to the principle of brevity, the letterers of these unique forms are adhering to the sound principles embodied in the oldest forms of lettering, such as the inscriptions on the old Greek and Roman temples. In all of these as few letters were used as possible, wide spacing was employed and the whole effect was one of combined simplicity and dignity.

But simplicity of style and excellence of lettering is not always sufficient to secure attention. The letterers who planned the inscriptions on the old temples knew they were ornamenting something that would endure for generations. They were reasonably sure, if not of appreciation, at least of a reading of the words they carved. But the efforts of advertising letterers today depend for their success upon a casual reading by an uninterested audience. The average magazine reader, for example, may be intensely interested in the mystery story that he follows through many "continuations" to the back pages of the periodical, but he is not vitally concerned with reading the story of your product. Hence the value of lettering that stands out from the page and forces itself upon his attention by its unique pictorial quality.

Department Store Dependence on Newspapers

THE recent charge of Senator McCumber in regard to the influence exerted upon newspapers by department stores for a low tariff may be easily disproved by a consideration of the actual facts in the case. Although the newspapers can get along without the department store, the department store cannot get along without the newspaper. In fact, the average department store depends upon the daily newspaper advertisement for its very existence. Proof of this may be found in the drop in department store sales that invariably accompany a pressmen's strike in any city.

Printers' Ink points out that although publishers are naturally anxious to please their advertisers, they know that advertisers are not in the habit of buying space in a publication simply because its editor's opinion coincides with theirs. They know that the only way to please an advertiser is to give him circulation. Advertising values must be founded on honest circulation and genuine circulation in turn can be built only on editorial merit. It must be remembered that both the department store and the newspaper are seeking the same thing—circulation, and that it is upon this circulation basis alone that advertisements are placed. There are many newspapers, of course, that are strongly in favor of a high tariff.

AUTOMOTIVE

Too Many Motor Truck Dealers

ONE of the most striking examples of multiplication and wastefulness of effort, and of destructive competition is furnished in the automotive truck industry. The distributing branch of the truck industry, weighed by the number of factors in it, is many times as large as it needs to be for distribution of the product that has been, or can be, moved by it, and it threatens to expand still further in the future unless some method of restraint is discovered. According to *Power Wagon*, "the distributing system of this industry is largely of the nature of a bubble which, unable longer to withstand the ever increasing internal pressure of unwarranted expansion, must inevitably burst, with disaster to the bubble and serious shock to the surrounding atmosphere."

The truck industry possesses a distributing system which includes nearly 24,000 dealers engaged in the business of retailing motor trucks and at no time except in the "boom" years of 1919 and 1920 have more than 150,000 trucks been

disposed of in a single year. The profits on six sales per year cannot possibly be a paying proposition. In the smaller towns the dealers change their lines from year to year or oftener in the search for a "fast-selling" truck, ask ridiculously low prices in order to salvage their investment, and "by the sheer weight of their numbers mislead truck makers into believing that production must be advanced to meet the pressing demand of the 'great unsold.'" And even in the largest markets of the country, the situation is not much different, except that a demand exists that can be measured.

Another source of annoyance and of diminished profit to the dealer may be found in the readiness with which the average dealer complies with the demands the customer makes when buying a truck. Lacking technical knowledge and unable to afford the services of a competent engineer, the dealer is often persuaded into making expensive changes which add nothing to the value of the truck.

New European Taxicabs Designed for Big Economy. Description of new French car designs, intended primarily for taxicab use, shows that these have been designed and built around the idea of superlative economy. This has necessitated few, simple, lightweight parts, small motors, compactness throughout to reduce chassis weight, general paring down of weight to permit use of small tires, etc. New Citroen, Renault and Fiat are described, and compared with Ford. The former has a four-cylinder motor of 2 11/16 bore and 3 15/16 inch stroke, a wheelbase of 111 ins., and a tread of but 46 ins. The narrow tread and small two-passenger body have brought the weight down to not more than 2600 with a driver and two passengers; can be carried economically on 24x3 1/2 tires, smaller than the average motorcycle. These cars in use in Paris average nearly 30 m. per gal. Details of the other taxicabs mentioned are given also. W. F. BRADLEY, *Automotive Industries*, 6-15-22, 1800 w. MAH.

Light Metal Research Will Affect Automotive Design. Increasing use of aluminum in the automotive field is noted, with a fairly general trend toward this metal or an alloy of it for pistons, crankcases, gear cases, most recently for connecting rods, and to come in the very near future what is practically an all-aluminum car. This has been completed and 12 more are now being built. It is said to weigh but 1,550 lbs., which is an even 1000 lbs. less than the average car of the same wheelbase, power and general characteristics. It is claimed that the wider use of this material will not only bring about lowered weight, which means reduced operating costs, but will also lower the first costs, since aluminum

The potential market for commercial cars totals 4,500,000. The estimates for motor buses are for current requirements only.—(*Commercial Car Journal*.)

can be machined so much more rapidly than the metals that it would replace that much money can be saved on the production cost. The same sized plant could turn out many more aluminum cars or parts than of steel or iron, which fact, in turn, would mean reduced plant equipment and maintenance costs, this being reflected in the final car cost. *Automotive Industries*, 6-8-22, 1400 w. MAH.

Motor Bus—Today and Tomorrow. Cost studies help to define the proper field of bus transportation, and from these it is found that the return on the investment is more important factor than the operating cost. Many experiments are being carried on, particularly in the search for greater passenger comfort. The newer limousine buses have made their appearance, and have been well received. The railway interests are less antagonistic. Other subjects treated are lower hung bodies, better lighting, heating and ventilation, the bus versus the private car, etc. WALTER JACKSON, *Automotive Industries*, 6-8-22, 7500 w. MAH.

Market Research Essential to Development of Tractor Design. Author makes this point at outset: Since farming methods are not likely to be changed to meet tractor requirements, tractor must meet farm needs. In order that tractor manufacturers may do the latter, research into farming methods, results desired, results actually obtained and other things of a similar nature will be necessary. All these things will influence future tractor design and construction. Figures are given of tractor production by years, distribution of Ford tractor sales to Jan. 1, 1922, by States' distribution of farms by size and actual number of tractors in the same sections, with their distribution, and similar data. E. A. WHITE, *Automotive Industries*, 6-8-22, 3200 w. MAH.

America in Airplane Research. Practically all aircraft activity may be classed as research and investigation, because the industry and its products are still in the embryo stage. However, much useful work is being done which will advance the industry rapidly in the near future. Within this classification come increased speed and reliability, development of helicopters, variable pitch propellers, landing field development, insurance and accident studies, larger engines, better fuel utilization, aerial cameras and photography, aerodynamic research, etc. ARCHIBALD BLACK, *Automotive Industries*, 6-8-22, 9300 w. MAH.

In England there are 600 motor trucking companies carrying freight for distances of 100 miles or more.—*Tractor World*.

CEMENT STONE BRICK

Grading Portland Cement

THE ENGINEERING NEWS-RECORD believes that the time is approaching when cement will be graded. Although the present standard cement specification is undoubtedly a great improvement on the standards of some years ago, it perpetuates the fallacy that all Portland cement is alike, or at least equally acceptable, provided it is just as good in a number of particulars. But it is pointed out that cement for different uses requires different properties. And at the present time there is difficulty in specifying cement qualities that will indicate these properties.

The choice of a particular brand of cement is frequently determined by the reputation for quality it has achieved among users. Since the raw materials from which the cement is made vary in composition, it is necessary for the manufacturer to allow for this, combining and treating these raw materials in accordance with their nature in order that the product may

be of proper quality. This calls for constant supervision and the making of frequent tests of the material during manufacture. In carrying out a process of this kind the element of character on the part of the manufacturer is important, his determination to maintain a standard of his own somewhat above the requirements set by the standard specifications.

But much more desirable than a reputation for excellence would be the distinct grading of cement for special purposes. This trend toward specialization is already being recognized by a few progressive manufacturers who, in their advertising, emphasize certain characteristics of their product. And as the value of these refinements in the manufacture become apparent to the consumer, insistence upon grading is almost certain to increase. Although there are some commercial reasons why one, and only one, cement standard should prevail, it is believed that they will in time bow to the demands of the user.

Solving Problems of Portland Cement Industry. Tells what Portland Cement Association is doing to improve cement, and its ultimate product, concrete. Covers work on specifications, research laboratory, improvements in manufacture; and economic bearing, public service and future developments. F. W. KELLEY, *Eng. News-Record*, 6-15-22, 3000 w. CS.

Investigation of Sulphide Cement. Results of tests by Illinois Division of Highways. Chemical analysis of cement disclosed presence 2% free sulphur, which when reduced resulted in .51% calcium sulphide. Briquettes showed decrease in strength with age. Caused by method employed in burning limestone and clay in kilns. Corrected by reducing blast nozzle from 18-in. to 10-in. and increasing pressure. H. F. CLEMMER, *Highway Engineer & Contractor*, 6-22, 500 w. CS.

Grading and Measuring Concrete Aggregates. Covers discussion of Indiana specifications for sand and gravel. R. C. YFOMAN, *Cement, Mill & Quarry*, 5-20-22, 1200 w. CS.

How to Use Concrete in Tree Dentistry. Illustrated article showing how to use concrete to repair trees. C. H. THOMAS, *Concrete*, 6-22, 500 w. CS.

Lime Plant without Precedent. Description of new plant with combination of most recent methods at Bellefonte, Pa. Use shaft at 52° angle, 390-ft. deep, through stratum parallel to that containing stone desired. Stone reached by four stopes with 30-ft. faces in three benches. Above ground plant rebuilt in latest design; illustrated. J. J. FITZGERALD, *Pit & Quarry*, 6-22, 3000 w. CS.

Slate as Permanent Roofing Material. Covers origin and importance, possible improvements in manufacture and classification, and laying of slate roof. OLIVER BOWLES, *Eng. World*, 6-22, 3000 w. CS.

Pure Calcium Carbonate, or "Iceland Spar." Limestone in most valuable form found in Iceland spar, occurs in California, Montana, Spain and Argentina. Covers properties and uses. OLIVER BOWLES, *Rock Products*, 6-3-22, 3000 w. CS.

Origin of Brick. Brief history of brick from time of Babylonians about 4500 B. C. to present time. *Builders Guide*, 6-7-22, 1000 w. CS.

Variation in Brick Strength. Results of tests on brick made by building material research committee of British Government. Writer believes 4-inch brick walls should be allowed in America for interior bearing and non-bearing partition, instead of present 8-inch minimum. W. CARVER, *Amer. Builder*, 6-22, 2000 w. CS.

Asbestos. Part VI. Covers some historical uses and modern mining and uses. JOSEPH K. COSTELLO, *Building Materials*, 6-22, 1800 w. CS.

Production, stocks, unfilled orders and shipments of face brick in 1920, 1921 and 1922. According to figures by the American Face Brick Association. — (*Brick & Clay Record*)

Correct Methods Lower Burning Costs. Comprehensive article telling what happens in kiln during burning, gives outline for efficient burning records, and suggests method for studying burning process. Illustrated. J. H. KRUSON, *Brick & Clay Record*, 6-13-22, 3500 w. CS.

Development of Asphalt Industry. Author traces steady growth in use of asphalt pavement from 1902 to date. Describes material itself, as to physical and chemical properties, tells how it is taken out of the ground, transported, stored, used in actual paving, and gives its advantages over other forms of pavement. Considerable reference is made to asphalt base of Mexican petroleum oil, as a possible large future source of raw material. Data given on Mexican, Trinidad, Venezuela and other sources. PREVOST HUBBARD, *Motor Truck*, 4-22, 5000 w. MAH.

Undesirable Diversity in Non-Metallic Mineral Products. Two processes involved in movement toward simplicity—elimination and standardization. Elimination by agreement between consumers and producers based on facts deduced from statistical data. Standards established on physical and chemical properties and requirements of consumers. Covers work already done along following lines: brick, slate, switchboards, sand, gravel, stone, paving block, feldspar, mineral fillers, mica. OLIVER BOWLES, *Cement, Mill & Quarry*, 5-20-22, 1700 w. CS.

Non-Metallic Mineral-Filler Industry of the South. Part one of an extensive treatise on this subject treats of the general mineral filler industry, what materials comprise the fillers, how they are used, and present business conditions with the producers. Then he takes up the fillers in order, giving detailed information about each. Some of those covered in this article are white clays, barite and graphite. W. M. WEIGEL, *Cement, Mill and Quarry*, 3-22, 3400 w. MAH.

DRUGS CHEMICALS

Bus Fares Lowered One-Third By Fuel Alcohol

THAT alcohol may eventually take the place of gasoline as a source of power is predicted by the *Engineering and Mining Journal*. This substitution would not only result in a cheaper fuel, but since alcohol is the product of vegetable growth it would insure an inexhaustible supply through the scientific cultivation of natural products.

It has been found, however, that alcohol for this purpose can be made only at a prohibitive cost unless the new industry operates in conjunction with other industries. To make the venture a success the alcohol factory must be able to produce cheaply a salable by-product or the alcohol itself must be manufactured as the by-product of another industry.

In South America it is said that considerable success has resulted from the use of alcohol as a fuel in internal-combustion engines. In Cuba there is strong indication that gasoline will soon be replaced entirely by wood alcohol, obtained from the waste product of the sugar mills. The aver-

age cost of gasoline in Havana is about 50 cents per gallon, while alcohol costs only 35 cents per gallon. Those drivers of automobiles for hire using the substitute have found that they can reduce fares by one-third and that the price charged still permits a fair margin of profit after operating expenses are deducted.

Another interesting experiment is being carried on in India, where alcohol is being produced from the flowers of the malwa trees. The daily output is said to be 10,000 gallons. And in New Guinea plans are now under way for the construction of a plant that is to cost \$1,000,000 for the production of alcohol from the nipa palm. It is proposed to produce 3,000,000 gallons of motor spirit per year, as well as 500 tons of paper as a by-product. This estimate no doubt is based on the success that has attended the cultivation of the nipa palm in the Philippines, where the sap forms the source of 90% of the alcohol produced there. It costs less than 10 cents per gallon.

Raw Materials of Chemical Industry. Popular lecture showing that successful development and establishment of chemical industry is primarily based upon supply of cheap and satisfactory raw materials. Discusses acid and alkali, lime and magnesia, aluminum and clay, fertilizers, metallurgical industries, bituminous materials, vegetable and animal fats and oils, naval stores and rubber industries, sugar starch, dairy industries, cellulose and textiles, leather, coal tar, etc. S. P. SADTLER, *Am. J. Pharmacy*, 6-22, 30 pp. CJW.

Hydrochloric Acid. Description of apparatus and method of manufacturing hydrochloric acid by direct union of hydrogen and chlorine. Gases obtained by electrolysis of solution of sodium or potassium chloride (sodium or potassium hydroxide is byproduct). Proportion of gases do not alter with alterations of current going through cells. Capacity will vary with number of cells connected on anode side of circuit, amperes per cell, efficiency of cells. Apparatus illustrated and process described. Fully protected by patents. H. K. MOORE, *Chem. Age*, 6-22, 1200 w. CJW.

Phosphoric Acid. Commercial production of phosphoric acid in electric furnace by condensation and electrical precipitation is now being successfully conducted. Methods of purification have been worked out and processes have been developed for manufacture of various high-grade phosphate products. Process should be applied to fertilizer production. T. SWANN, *J. Ind. Eng. Chem.*, 7-22, 1500 w. CJW.

Sulphur in Chile. Sulphur deposits of Chile are little known but form an important part of world's known reserve of mineral. Industry still in its infancy, climatic conditions complicating mining.

Output in 1918 was 19,557 metric tons. Estimated resources 3,418,000 tons. Description of process of mining and refining. HERBERT G. OFFICER, *Eng. Min. J-Press*, 6-10-22, 3000 w. CJW.

Calcium Arsenate. For every 100 lbs. of calcium arsenate which is made, approximately 40 lbs. of white arsenic is necessary. Supply of arsenic annually consumed by this product thus far is not large, but it is appreciable percentage of total supply which is relatively stationary quantity. Use of arsenate for boll weevil will increase but at rate which cannot be anticipated. It will depend upon supply of arsenic which is available, upon price of cotton, upon yield of cotton per acre and upon price of arsenate. In addition other uses of arsenate are increasing annually, notably those which have to do with garden truck produce. Finally, calcium arsenate has been recently recommended as effective means of preventing alfalfa weevil from spreading. Barely possible that this use may eclipse its use as cotton insecticide. Other uses in various insecticides can easily outbid cotton market for available white arsenic. H. W. AMBRUSTER, *Chem. Met. Eng.*, 6-21-22, 3000 w. CJW.

Hydrogen Peroxide. Description of experiments carried out on manufacture of hydrogen peroxide by reaction of emulsion of barium peroxide and water upon carbon dioxide under pressure. Greatest difficulty encountered was introduction of peroxide into reaction chamber. Fairly satisfactorily settled by use of simple single-stroke plunger pump using ordinary brass check valves. Average recoveries of hydrogen peroxide were 80% to 85%, though individual experiments gave as high as 90%. Product proved very satisfactory at first but later developments indicated instability, though cause was never found. H. A. DOERNER, *Chem. Met. Eng.*, 6-14-22, 1500 w. CJW.

Ammonia is being manufactured from the nitrogen found in molasses in a sugar refinery in France.—*Steam Shovel and Dredge Mag.*

Urea. Urea is of value as stabilizer for explosive mixtures, constituent of varnish and ingredient of transparent celluloid used for photographic films, factor in organic syntheses and medicinal preparations. One important latent possibility is its use as fertilizer. Process of manufacture described consists in preparation of ammonium carbamate, autoclaving to cause partial conversion to urea, distilling resulting sludge to separate unconverted ammonia and carbon dioxide and condensation of distillate with additional gas to form new charge. Small scale plant described. Cost of ammonia will constitute principal cost of urea made by this process. It therefore unquestionably possesses important commercial possibilities. N. W. KRASE and V. L. GADDY, *J. Ind. Eng. Chem.*, 7-22 6000 w. CJW.

Black Pigments. Continued article, present installment continuing discussion of carbon black. All attempts to increase yield has been at cost of quality. Product carefully bolted through nine wire screen and then agitated to remove air so as to pack more compactly. Method of supplying gas described. In using black, fact that it is hygroscopic must be kept in mind; moist black cannot be ground, as it will liver and not mix properly with vehicles. If moisture is in excess of 1.6%, black should be dried. H. L. BLACHFORD, *Can. Dyer and Color User*, 6-22, 1000 w. CJW.

Precipitating Cyanide Solutions. Careful tests of suggestion that acetylene might be used for this purpose show that, when free from hydrogen sulfide, acetylene has no precipitating power on cyanide solutions of silver. J. GROSS, *Reports of Investigations, Bureau of Mines*, No. 2346, 1 p. CJW.

Ammonia Oxidation. Under present conditions salt-peter has a slight advantage over ammonia as source of strong nitric acid. The conversion cost and nitrogen cost (usually) of ammonia are less than corresponding costs of sodium nitrate, but this advantage is more than offset by necessity for concentrating nitric acid in ammonia process. Advantage of retort process probably increases as scale of manufacture decreases. If price of ammonia falls then slight advantage of retort process will disappear. Two possible uses for ammonia oxidation at present are: Lead chamber or "nitration" sulphuric acid plants, because of ease of control and uniformity of supply and in production of weak nitric acid, which can be utilized by a few industries. GUY B. TAYLOR, *Chem. Met. Eng.*, 6-28-22, 1600 w. CJW.

Ozone. Powerful bactericidal and deodorizing agent. Low voltage must be employed. Dielectric in ozone machine should be of some material that is not affected by moisture and can be readily cleaned. There must be accessibility for cleaning every part of equipment. Concentration must be controlled. Should be able to determine concentration accurately. H. HAMILTON, *J. Am. Soc. Heating Ventilating Eng.*, 4-22, 1500 w. CJW.

Hydrogen Sulfide in Foods. Method is described for determination of hydrogen sulfide evolved when foods are cooked at 100°C. or higher. Involves distillation of sample with steam under pressure and gravimetric determination of sulfide as barium sulfate. Green corn gives considerable quantities of substances other than hydrogen sulfide which reduce potassium permanganate and this method makes study of these products possible. E. E. KOHMAN, *J. Ind. Eng. Chem.*, 6-22, 2250 w. CJW.

Liquid Soaps. Ordinarily consists of mixture of water, glycerine and potassium soap of coconut oil. Clear product depends upon grade of materials used and on care of manufacture. Oil of Cochin quality furnishes good base for high-grade product, though highest quality liquid soap made from oil containing not over 5% fatty acids. M. DONIGER, *Chem. Met. Eng.*, 6-14-22, 750 w. CJW.

Indicator. Phenolphthalein not always satisfactory as test for free alkali in soap. May be due to temperature of soap or to presence of carbonates. Suggests solution in alcohol, in which carbonates are insoluble. K. L. WEBER, *American Perfumer*, 6-22, 750 w. CJW.

Glycerine Recovery. Crude lyes purified by precipitating out soap and fatty acids as insoluble salts, usually of aluminum or iron. Detailed directions given for process. Limits of reaction at close of treatment are 0.01% acid to 0.02% alkaline. Evaporation of lyes usually carried out in single or double effect vacuum effect evaporators. Single effect used in most soap works. Operation of removal of salt until half-crude stage is reached and preparation of 80% crude glycerine described. Losses are avoided by preventing sudden rises in vacuum, because this condition causes crude liquor to be carried over into catchall. Decrease in rate of evaporation of any evaporator is most frequently due to

New Mechanical Den and Excavator

Fertilizer manufacturers will see at their convention this year a working model of this Sturtevant den and excavator. This acidulating unit consists of automatic dust and acid scales. The scales discharge into a new type of leakless mixer, without plug or plows, which violently agitates the acid and rock, with no dead spots, and therefore causes quick chemical reaction within the mixer before discharge into the den. When these correctly weighed and intimately mixed batches have filled the den, the sides are loosened and the front raised, within thirty minutes after the last batch has been deposited, and the beautifully honeycombed block of acid phosphate is seen ready to instantly cut out. The mechanical excavator and aerator is now started and the den sides slowly and automatically move backward as the fan cutters advance shaving thin slices away from the block of acid phosphate, at the same time aerating the surface and delivering the crumbly, granular acid phosphate to the pan conveyor which removes it to storage. This operation simply removes the surplus water moisture, thus hastening the formation of water crystals, and leaving no lumps, it is claimed. There is said to be no reversion in the pile, yet sufficient moisture is retained to complete the chemical reaction and cut down the insoluble to a minimum.

—(Commercial Fertilizer.)

slating-up of tubes. Methods of preventing this. WALTER E. SANGER, *Chem. Met. Eng.*, 6-28-22, 4000 w. CJW.

Indigo. Continued article, present installment discussing use of indigo in dyeing, vats, the hydrosulfides, and printing with indigo. Indigo valued because of its fastness to repeated washing and wear. Any fading will be merely weakening of intensity of hue. Addition of bone glue previous to dyeing gives bright, beautiful reddish casts. W.M. B. NANSON, *Cotton*, 6-22, 2000 w. CJW.

Marketing Chemicals. Various component departments co-operating in marketing function are illustrated in following steps:

1. Locate the market.
Sales research or engineering.
2. Interest it in the product.
Advertising.
3. Classify prospects.
Credit.
4. Consummate sales.
Sales.
5. Deliver the product.
Traffic.
6. Keep customer satisfied.
Trouble dept., or sales source.
7. Collect the bills.
Collection (or credit).

There follows general discussion of the question of advertising in chemical industry, under three heads of planning, production and statistical. Chemical advertising limited to direct advertising and advertising in technical and trade periodicals. Problems must be solved by aid of advertising experts. Advertising agency and advertising department complimentary and not interchangeable. CHARLES WADSWORTH, *Chem. Met. Eng.*, 5-17-22, 2000 w. CJW.

Fat and Oil Industries. Fats play an important part in economic development of any country. Important to know exact composition of fats and oils, and limits of variations in chemical and physical characteristics of pure oils. Research work of Bureau of Chemistry on fats and oils discussed as well as its limitations. Believed that Governmental laboratories should investigate fundamental problems, and that results should be made public as completely as possible. Services of Bureau at service of industries in consulting capacity and work of value to the industry will be undertaken if possible. W. W. SKINNER, *Chem. Age*, 6-22, 2000 w. CJW.

Artificial camphor made from coal tar has broken Japan's long established monopoly on this article.—*Steam Shovel and Dredge Mag.*

CEREALS • MILLING

The Miller's Share in the Profits

A WRITER in a recent issue of *American Miller* discussing the interesting question of what part of the consumer's dollar spent for bread goes to the miller, says that this question has been answered by data recently published by the Joint Commission of Agricultural Inquiry which shows the division of the dollar in 1921 between production and distribution agencies and between costs and profits. According to these figures the retailer of bread receives 16.6 cents, of which 15.7 cents constitute operating expense and 2.9 cents are profit. The baker gets 42.9 cents, of which 12.3 cents

represent the cost of manufacture, 16.4 cents selling cost, 8.5 cents overhead, and 5.7 cents profit. The producer of the wheat receives 28.1 cents. This, it is pointed out, accounts for 89.6 cents of the dollar. Transportation to the mill costs 2.6 cents of the dollar; transportation from the mill 4.4 cents, leaving only 3.4 cents to divide between the miller and the grain man, which must cover cost and profit. Although the margin of profit for the producer of the wheat is not large, he is today receiving as much of the dollar spent by the consumer for bread in 1921 as he did in 1913.

Dust Explosions. Flour milling industry has made significant progress in controlling dust explosions and reducing losses from this particular cause. Federal investigation of dust explosions undertaken at request of millers in 1913. Summary of dust explosion losses in various industries. Each explosion has average loss of \$270,000. Dust removal in grain elevators very important. Co-operation of millers necessary. DAVID J. PRICE, *Chem. Met. Eng.*, 6-28-22, 3500 w. CJW.

Soft Wheat Milling. To bring soft wheat up to high standard of milling, it is necessary that wheat be not only graded as to quality and test, but also as to moisture. Even tempering important. Difficult to mill wheat that is made up of blend of wheat varying in moisture of 2% to 4% and left in bin for a time to equalize moisture. Milling soft wheat with uneven tempering interferes with color and ash. Hours of temper should depend on moisture already present in wheat. After tempering, wheat should be scoured in such a way as to remove little of bran and as much as possible of fiber, beard and stem. Methods of tempering include steam, heat and water. Water and steam preferable. JAMES J. SCHEURICH, *Dixie Miller*, 6-22, 2500 w. HHH.

New grain elevators have been installed at the port of Dunkirk by means of which it is possible to discharge vessels at the rate of about 2,000 tons per diem, all cargo discharged being sacked by the elevators. It is also stated that by this method the loss of weight through discharge has been reduced from 0.92% to 0.42%.—Nauticus.

Standardization of Bakers' Materials. Any system of standardization or defini-

Corn prices, dollars per bushel, 1912-1922.—(*Magazine of Wall Street.*)

tions of a product should have two objects in view: First, to afford protection to buyer or consumer of product, and second, to prevent adulteration of product by producer and unfair methods of competition within industry in order to protect honest manufacturers against unscrupulous ones. Importance of knowing relative value of shortenings and of demanding purity in bread ingredients. Co-operation between shop and laboratory essential. *Baker's Helper*, 7-22, 2500 w. HHH.

Cakes and Chemistry. A series explaining principles underlying methods of chemical analysis. Current instalment presents analyses of butter and margarine and milk and butter standards, with several tables of comparisons. WILLIAM JAGO, *Bakers' Helper*, 6-1-22, 3000 w. WRB.

Importance of Water in Baking. Recent investigation shows that mineral matter held in solution and suspension in water has far-reaching effect on doughs during fermentation and baking stage. Soft water not well adapted, and

alkaline water has detrimental effect on dough. To overcome differences in water, compound of inorganic salts added to soft water will make it fit for baking purposes. European investigators find that better yeast can be cultured in hard water than in soft water. *Bakers' Weekly*, 6-25-22, 2000 w. HHH.

Biscuit and Cake Manufacture—II. In biscuit practically only value derived from use of milk comes from butter fat contained. May be replaced by equivalent amount of butter, and milk is therefore not recommended. In drop and pound cakes butter fat of value as food, but milk also important because of its emulsifying power. Since this is necessary in securing good finished product, milk is recommended. In sugar water tops emulsifying power of milk is absolutely essential for manufacture of good product. Butter fat of milk can be replaced by other oils if desired. W. PLATT, *Chem. Age*, 5-22, 3000 w. CJW.

Art of Bread Making. New standards needed for science and art of bread-making, new standards for service and new methods of attack in competition and ways and means for eliminating waste of time, material, forms, etc. Desirable to reduce all classes of pan bread to unit weight to volume system, and to establish standard for cubic measurement of pan for each ounce of dough and eliminate many of sizes and shapes now being made. R. L. CORBY, *Bakers' Weekly*, 7-1-22, 2000 w. HHH.

The manufacture has been begun in New Zealand of a flour made from the lean meat of sheep and cattle, treated by a process that removes all but less than 8% of water.—*Steam Shovel and Dredge Mag.*

ELECTRICITY

Electric Home-Heating Practical

THAT the heating of homes by electricity may in a few years no longer be considered a luxury, but the cleanest and most economical method of heating, is indicated by its popularity in the West. According to the *Journal of Electricity and Western Industry*, there has been more active interest shown in this field by the public than in almost any other line of electrical activity.

Perhaps the most interesting part of the development has been that it has not required excessively low rates on the part of the power companies. Although electric heating is still a little more expensive than other methods, a scientific

use of intermediate and low heats makes this difference comparatively insignificant, when the increased cleanliness and comfort are taken into consideration.

Although power companies in the Intermountain district have protested in the past against the electric heating load, it has been found that such a load will in reality prove advantageous, especially if some means can be devised to bring it on at "valley" periods of the day. A water-heating system which will utilize current during the night, warming the house through the stored heat in the daytime, has been suggested as one means of bringing about the desired end.

Load and Generator Capacity. Demand factor is ratio of maximum demand of any system to total connected load of system. Load factor is ratio of average power to maximum power during certain period of time. Principal applications of electric power in coal mines are ventilation, electric hoists, crushers and washers, shop and tippie machinery, pumps and booster fans, mining machines and locomotives. Each of these applications is discussed and load curves shown. CARL LEE, *Coal Age*, 6-22-22, 2000 w. 13 curves. CJW.

Estimated increase in h.p. motors in Western mines. The increase is typical. The only lagging is that of prime movers, which is due to fewer mines generating their own power—and more purchasing from power companies.—(*Journal of Electricity and Western Industry*.)

Inductive Interference Antidotes. Causes, effects and means of elimination or reduction of inductive interference are discussed. Chief antidotes for mitigation of inductive interference are elimination of harmonics, other than the fundamental, the balancing of residual currents and voltages, the transposition of telephone and power lines and the separation of telephone and powers lines. Harmonics are due to the design of the generator and motors, to the operation of transformers at such load that the iron approaches magneto saturation and to the presence of arc lights and accidental arcing. Balanced circuits should be used. Residual currents are due to unbalanced loads, grounds in the line, unbalanced capacity and leakage, grounding of transformer bank at other than neutral points, opening of a phase, and charging and discharging of electrolytic lightning arrestors. Residual currents and voltages should be balanced. W. J. WOPAL, *Telephony*, 6-24-22. IG.

motors are increasing widely, and each new one brings up some new problems. In using these motors to drive ammonia compressors, there are number of special problems, and one is starting. Author discusses this from all viewpoints, including higher starting torque required, special case of direct-connected unit, difficulties peculiar to use of large flywheels, variation in pressure drop in by-pass, and many other points of importance to operating engineer. A. R. STEVENSON, JR., *Power*, 5-16-22, 4600 w. MAH.

Electricity in the House. The seventh and concluding paper in this series which went into detail on proper wiring of each room in modern home. This instalment deals with halls, stairs and porch. It brings out the fact that today in a modern home the lighting is 28.5%, the power 34.5%, and the appliance load is 37% of the total bill each month for electricity. M. O. WHITTON, *Amer. Architect*, 7-5-22. 2500 w. EMCC.

Operation of Traction Type Elevator Machine Alternating Current Motor

Controller. The different parts of a controller for a single speed alternating current elevator motor are explained, and the circuits are traced out through the controller and motor for one direction of the machine. W. ZEPERNICK, *Power*, 7-4-22. IG.

Tests for Electrical Transformer Oils.

Function of transformer oil is to dissipate heat generated in transformer and at same time provide adequate electrical insulation between surfaces of wide potential difference. Initial requirements for a good transformer oil are three: High electrical insulating quality as indicated by dielectric strength and resistivity; ability to dissipate heat as indicated by viscosity, specific heat, heat conductivity, cold test, etc.; suitability from the standpoints of evaporation loss and of safety from fire hazard as indicated by the flash point. Durability or ability of the transformer oil to retain its essential original properties, even after prolonged use, is also just as important. Transformer oils may deteriorate in service as far as electrical insulating efficiency is concerned through chemical formation of water, of organic acids, or soaps derived from such acids on the metallic components of the transformer. Oils should be provided which will pass durability test to cover decrease in insulating value due to oxidation. Deterioration as regards heat dissipation is somewhat more complicated. Oil must absorb heat generated in transformer core and windings, circulate to a cool surface and there transfer the heat. Viscosity of the oil should not change due to evaporation or chemical processes, otherwise, circulation is impaired. Chemical changes taking place in the oil seem to be due mainly to oxidation, which is accelerated by the catalytic action of the metals, resins, metallic compounds or even atmospheric dust which comes in contact with it. Various oxidation tests are described. Deposit or formalite test, iodine addition values and iodine substitution values and sulphuric acid absorption tests should also be made. E. T. DELBRIDGE, *Oil News*, 7-5-22. IG.

FUEL POWER

Runaway Prices for Coal Coming

IF production in the coal fields is not resumed by August 1, it is believed that panic among both industrial and domestic users of coal will force prices up to a point that will increase manufacturing expenses. *Coal Age* points out that production, measured against demand, not consumption, sets the price. And from now on demand will be equal to consumption plus what the buyer would like to store against next winter's needs. As the impossibility of meeting this demand becomes evident, the industrial users of coal will bid against each other to secure coal to carry over the winter.

A consideration of the rapidly diminishing stock of coal now on hand will prove that the danger of a coal famine has not been exaggerated. There are said to be practically no available above-ground supplies of anthracite except those held by retail dealers and that already in residence cellars. Pea is the only size that can be had from producers in quantity. The hard-coal mines have no over capacity with which to make up deficiencies and there is no non-union production to supplement that now on strike. It is asserted that even if the anthracite mines were at work now, producers would be obliged to allocate shipments. Moreover, every day's output lost from now on will sharpen the demand to a point where runaway prices for some of the independent coal will be paid.

In addition to this potential shortage of anthracite, the country faces a situation with respect to bituminous coal that under similar circumstances in the past has resulted in panic prices and exhibited all the symptoms of a shortage. In spite of the fact that extensive preparations were made for the strike, the coal in storage has decreased until by August 1 it is expected that the reserve stock of coal will amount to only 23,000,000 tons.

"Judging from the history of the past seven years," says *Coal Age*, "an above-ground stock of bituminous coal of only 10,000,000 tons represents an impossible situation in this country. During 1917 and 1918, when consumption was at the rate of about 40,000,000 tons per month, there was a serious coal shortage, when stocks were as low as 20,000,000 tons—that is, when the average for the country was equal to two weeks' requirements. Consumption is now estimated to be at the rate of 34,500,000 tons per month and two weeks' supply is therefore some 17,000,000 tons. Although skating close to the danger mark, the country had not by July 1 reached a crisis. Some time before August 1 that point will have been reached if production is not resumed. In other words, by that time, but for successful intervention by Washington, the united mine workers will have the country where it wants it."

Coal and Oil. Series of charts showing operating efficiency with coal in melting of metals, treating steel at various temperatures, burning of brick, lime, etc., and melting of glass and boiler efficiency.

Accompanying chart shows amount of oil required to produce same results as one pound of coal in same or similar furnace. Examples are given to illustrate their use. C. H. Butz, *Heat-*

Forging Treating, 6-22, 2500 w. C.J.W.

The U. S. Bureau of Mines has succeeded in producing fuel from ordinary straw.—*Tractor World*.

The amount of oil required to produce the same results as one pound of coal in the same or a similar furnace. See "Coal and Oil" digest.

Benzene and Motor Fuel. Benzene is excellent fuel for internal combustion motor. Calorific value of benzene is approximately 13% higher than that of gasoline. Tests show increase of 22.7% in miles per gal. Marked reduction of any tendency to "knock" under heavy loads, and ignition may be advanced to greater extent with view of eliminating this knock and its effects on engine. Benzene permits of leaner mixture. J. J. LAWTON, *J. Ind. Eng. Chem.*, 7-22, 600 w. CJW.

Blends of Hydrocarbons. Study of the effect of benzene and other aromatic hydrocarbons upon tendency of paraffin-base gasolines to knock or detonate. Use made of apparatus for measuring detonation by bouncing pin method. Most of determinations made on mixtures of kerosene on account of its greater tendency to detonate. Standard was paraffin fuels containing small amount of xylidine which exerts powerful suppressing effect on detonation. Simple basis for determining amount of benzene nec-

type are fired by mechanical burners of special design. Requires force of 13 men. Oil piped to give same pressure at all boilers. Peabody-Fisher wide-range oil burner used. Plant easily changed to coal if desired. Details. POWER, 6-13-22, 1200 w. CJW.

Evaporation. Investigation of mechanism of evaporation of liquid into gas as applied to such processes as are found in gas scrubbers, humidifiers, dehumidifiers, water coolers, air driers, etc. Formula is established for calculating humidity of air from wet- and dry-bulb thermometer readings. Coefficient of heat transfer divided by coefficient of diffusion equals humid heat of gas; W. K. LEWIS, *Mechanical Eng.*, 7-22 1200 w. CJW.

Cleaning Gas Piping. Much trouble and expensive repairs are often caused by collection of foreign matter in consumers' gas lines causing flow of gas to be retarded with result that distribution is irregular. Damp cellars are

Combustion Research. Many of the important engine problems of today are mentioned, and the work which is being done upon them. These include detonation, its causes and effects, possible remedies for it, the effect of diluents upon it, the efficacy of dopes, flame propagation, turbulence, pressure rise during combustion, effect of small changes in initial temperatures, etc. HERBERT CHASE, *Automotive Industries*, 6-8-22, 5500 w. MAH.

Present-Day Boiler-Room Operation. Practical article on features of modern boiler room work, including efficiency of equipment, of load curve, of extensions, daily load peak, method of operation, rapid changes in load, emergency conditions, thunderstorms, loss of load, etc. I. E. MOULTHROP and R. E. DILLON, *Power House*, 5-5-22, 3100 w. MAH.

Significance of Chimney Draft. Notes on need of chimneys, pulling power of stacks in relation to their height and area, effect of wind pressure and

Analysis of three coals, made by Prof. S. W. Parr, of the University of Illinois.

essary to add to paraffin fuel in order to obtain given effect is: Up to concentration of 70% by molecules, effectiveness of benzene for suppressing detonation varies as square of its molecular concentration. THOMAS MIDGLEY and T. A. BOYD, *J. Ind. Eng. Chem.*, 7-22, 3500 w. CJW.

Oil-fired Boilers. Description of oil equipment at Amoskeag Mfg. Co., Manchester, N. H. Sixty-four vertical fire-tube 1500 sq. ft. boilers of Manning

prolific cause of rust stoppages as well as piping exposed on walls. Compressed air has proved to be effective agent in remedying this difficulty and after continued use has come to be recognized method for removal of these stoppages. Method of operation. J. T. GRIFFIN, *Compressed Air Mag.*, 7-22, 2000 w. CJW.

Boiler Tests. Errors entering into boiler tests are determination of water and coal used. Error in obtaining BTU in coal burned may easily reach 2.5% (weighing, 0.5; estimating fuel in furnace at start and stop, 0.5; variation in moisture, 1; failure of heat-value sample to represent bulk, 0.5) and water evaporated may be at least one per cent out of way, hence efficiency reported may be 3.5% too high or low. It is absurd to assign values carried out to 0.01% to items which cannot possibly be measured so closely. ALFRED COTTON, *Mechanical Eng.*, 7-22, 2500 w. CJW.

methods of staying by guy ropes. Besides explaining all these points, tables are presented, and charts in which results may be read off without figuring. POWER HOUSE, 5-5-22, 2200 w. MAH.

Making and Care of Flexible Steel Ropes. Author defines and describes wire ropes or cables, including considerable history of the early days of steel cable manufacture. He describes spooling, stranding and squeezing, and twisting, also proper materials, strength, tests, lubrication, inspection, abrasion, etc. W. VOIGHTLANDER, *Iron Age*, 4-29-22, 2400 w. MAH.

GLASS POTTERY

All Kinds of Glassware in Demand

OWING to the greatly increased demand from soft-drink manufacturers for bottles and containers, it is believed that producers of this type of glassware will be very active during the summer. Whereas the sale of beer over the bar resulted in comparatively small sales of the beverage in bottles, soft drinks must be sold bottled, and this has actually increased the glass consumption, according to some estimates.

According to *Glass Worker*, the market for glass products is being aided greatly by the fact that stocks have been low in the hands of distributors and retailers. Although these stocks are now being replenished, it appears from the nature of the orders received that most of the glass and glass products going from factories is finding an unusually short journey to the ultimate user.

The unexpected demand for plate-glass by the automotive industry and by the increasing building operations continues to keep plate-glass manufacturers at capacity. There is every indication that demand will continue active for the remainder of the year. Window glass is reported to be moving from factories in steady volume. Orders have kept up very well and July probably will be a very active month. Stocks at factories are yet ample to take care of demand. They have been reduced, but all specifications still can be filled without much trouble. How long this favorable situation for the buyer will continue is likely to depend entirely upon the course of demand in the next few weeks. It is pointed out that there are many hundreds of buildings under roof which will need glass even if the rail strike checks transportation.

Cords in Glass. The refractivity, viscosity and expansion coefficient of cords generally differ from those of mass of glass. Methods are described for rapidly ascertaining relative values of these properties. This information, together with knowledge of batch ingredients and possible impurities, may afford in certain cases means of determining cause of the cords. F. TWYMAN, *J. Am. Ceramic Soc.*, 6-22, 1500 w. CJW.

Stained Glass. Third paper dealing with historical periods. Glass-making for churches in 14th and 15th centuries, with some illustrations; also discusses work of 16th century, at which time the art commenced to change from that of making transparent glass to the painting of pictures. JOSEPH G. REYNOLDS, JR., *Amer. Architect*, 6-21-22, 3000 w. EMCC.

Venetian Glass Industry. Revival is noted in Venetian glass industry since war, and in glass beads and trinkets, but as art and as great and beautiful industry present wares do not come up to achievements of past. Various novelties mentioned. *Crockery and Glass J.*, 6-29-22, 500 w. CJW.

Value of Colored Glassware. Writer discusses the value of colored glassware in the home. Heretofore flowers were depended upon as attention arresters, but colored glassware objects are now sharing popularity. Proper colors to use are suggested, suggestions being based on color scheme of room. *National Glass Budget*, 6-10-22, 700 w. WRB.

Glass History of England. History traced from 1549. Suggests that productive capacity might be 50% greater than at present. Only fringe of development of glass furnaces has been touched. Very marked advances in machinery in last decade. W. E. S. TURNER, *National Glass Budget*, 6-17-22, 1500 w. CJW.

Glass Making. Largely historical with special reference to manufacture of bottles. Glass-blowing machine one of most important inventions. Very brief description of process. A. W. BITTING, *Pacific Drug Rev.*, 7-22, 1400 w. CJW.

Charging Tank and Pot Furnaces. Weight and volume of batch charged into tank furnace has decided effect on efficiency of melting both from fuel as well as quality of glass point of view. Best results by continuous feeding at short intervals. Use of dog-house avoids difficulty of charging. *National Glass Budget*, 6-17-22, 750 w. CJW.

Glass House Losses. First loss is shrinkage of raw materials (10% to 15%) due to volatilization of part of chemicals used, which is unavoidable. Amount of loss by breaking pots varies according to location of break. Most of that in bottoms of pots could be saved. Loss occurs in mixing room and store room for raw materials. Five to ten pounds loss in sweepings for each pot filled. In electric light bulb plants glass used in gathering with thread could be saved (10-15 lbs. per pot in 24 hrs.). In plants manufacturing different kinds of glass, loss is due to mixing cullets of different kinds and by mixing different kinds of batch and cullet. Much waste from broken glass, which could be obviated in part by use of screens to catch waste and broken glass. Many other wastes, as of power, light, etc., might be noted. HENRY W. HESS, *Glass Worker*, 6-17-22, 1000 w. CJW.

National China. Description of process used by National China Co., of Salineville, O. Material first mixed in proper proportions, ground and mixed with water to form "slip." Then passes through fine mesh of silk to presses by means of pressure pump. Water removed under high pressure, clay run through pug mill and then formed into articles either by hand or in presses. Green ware allowed to dry thoroughly, inspected and burned. Glaze is applied in dipping room, ware again dried and then fired in glost kiln with natural gas. Decorations made to order—either hand painted, stamped or by means of decalcomania paper. *China, Glass and Lamps*, 6-12-22, 1000 w. CJW.

Tableware. Comparative tests of American and foreign tableware. American ware superior when tested in resistance to either crazing or sudden temperature changes. American hotel wares withstood much greater impact than imported wares, and domestic earthenware and china for household use was superior to foreign chinas tested, which were brittle. Resistance to chipping at edge appeared to depend more on design of edge and angle of inclination of rim than on inherent properties of bodies. All glazes were found to be unaffected by boiling in alkaline solution for 24 hrs. H. H. SORTWELL, *J. Am. Ceramic Soc.*, 6-22 4500 w. CJW.

Firecracking in Terra Cotta. Firecracking is characterized by appearance of sharp, hair-line cracks extending into body. All bodies showed tendency to firecrack when cooled rapidly and all were free from cracks when cooled slowly. Rate of cooling more important than composition or physical properties of body. Sandy clays showed more tendency to firecrack than non-sandy vitrifying clays. Greatest tendency to firecrack was found on body with all grog finer than 40 mesh, but body with all grog coarser than 40-mesh did not appear to have much less tendency to firecrack than average. Increase of grog reduced tendency to firecrack. Kind or source not as important as size and amount, but this is less important than kind of clay. E. C. HILL, *J. Am. Ceram. Soc.*, 6-22, 4000 w. CJW.

Porcelain not fired in a kiln, but perfected by a secret process of cold hardening, is reported from Germany.—*Steam Shovel and Dredge Mag.*

An unknown malady is attacking the stained-glass panes of cathedral windows in Europe. The sickness makes the glass flake off in small pieces until the panes are so thin they crumble at the touch.—*Steam Shovel and Dredge Mag.*

LEATHER

Shoe Production Per Employee Increasing

THE willingness of employees in the shoe industry to accept wage reductions has had a favorable effect not only on employment but on the operation of plants in the large shoe centers. United States Government figures for June indicate an increase of 17% in the employment of workers in the shoe shops of the country, but wage increase has been only 10%.

The International Shoe Company is reported to be employing 21,000 persons, and the Endicott-Johnson Company from 14,000 to 15,000 workers. Each is making from 120,000 to 125,000 pairs of shoes daily. The International company requires a larger number of employees because it makes many women's shoes, which, because of the number of different styles, call for a greater amount of labor.

American Shoemaking points out, however, that it is doubt-

ful whether large increases in employment will occur, for the reason that the present objective among manufacturers is to reduce production costs as much as possible. New machines are being set up and new systems devised for the purpose of simplifying the making of shoes and reducing production expense.

Another circumstance affecting employment in the shoe industry is the fact that production per average employee is increasing. According to figures recently compiled by several large concerns, each man helps to make more shoes a day, so that fewer men are required to make our total production of 1,000,000 pairs a day. For this and other reasons there is a surplus of labor, and it is still true that the demand for workers in shoe shops is not as large as is the supply.

Outersole Sorting. Much depends for the quality of the ultimate shoe upon the care and intelligence of the outersole sorter. Practice of sorting by weight only should be replaced by sorting by the hardness and firmness. Such practice relieves turn laster of much labor and adds to uniformity of quality. *Amer. Shoemaking*, 6-22, 900 w. WRB.

Syntans. Artificial tanning materials manufactured from phenol, sulphuric acid, 40% formalin and water. Phenol may vary. Manufacture consists of sulphonation of phenol derivative by sulphuric acid, condensation of this product in presence of formalin and partial neutralization by caustic soda. The products are soluble in water and contain both free sulphonic and hydroxy groups. Actual constitution not known. Precipitate gelatin, mix well with tanning extracts and allow of quick tanning with production of good leather. Should have good future. *G. DESMURS, Canadian Dyer and Color User*, 6-22, 750 w. CJW.

Chrome Tanning. Measurement of fixation of chrome by hide substance after 8.5 months' contact with chrome liquor of various concentrations showed that

The manufacturer's distribution of the dollar the retailer pays for shoes. (By the Joint Commission of Agricultural Inquiry.)

maximum fixation occurred in chrome liquor of concentration of 1.5 grams chromium oxide per 100 cc. of solution. The chrome collagen compound formed in this liquor proved to be an octachrome collagen, showing that combining weight of collage in as low as 94. Changes tak-

ing place when tetrachrome collagen is in contact with chrome liquors over similar period of time have been measured, showing that the formation of tetrachrome collagen is not strictly reversible. The findings support the view that "adsorption" of chromium from chrome liquors by collagen is chemical reaction. *A. W. THOMAS and M. W. KELLY, J. Ind. Eng. Chem.*, 7-22, 1800 w. CJW.

Dyeing Skins. Conclusion of two-part article, giving methods and recipes for dyeing black on rabbit skins, dyeing skin rugs and mats in process of renovation, redyeing furs, the use of logwood blacks, cleaning by chlorinating, dyeing imitation sable skins, how to discover presence of sulphur in wool, and process of dyeing naturally white skins, or skins with white points and various shades of browns, leaving the points white. *Can. Dyer and Color User*, 5-22, 2500 w. WRB.

To determine horsepower transmitted by a leather belt, measure span of slack side as on sketch. Then measure sag, which is the greatest vertical distance between belt and straight line connecting contact points. Next measure span and sag of tight side, observing points of "making and breaking contact." In table, find tension corresponding to span and sag of slack side, which call "A." Then tension corresponding to span and sag of tight side, which call "B." Subtract "A" from "B"; multiply by width of belt in inches; multiply by thickness in inches; multiply by outside diameter of one pulley in inches; multiply by r. p. m. made by pulley; multiply by 0.000007933.

Data for measuring horsepower transmitted by leather belts. (W. F. Schaphorst in the National Engineer)

IRON STEEL

Large Steel Stocks at Mills

IT would serve no good purpose to foster the illusion that the coal strike curtailed the production of steel, says *Steel and Metal Digest*. On the other hand, it is pointed out that it increased production. In February and March a considerable part of the heavy buying of steel occurred because buyers were afraid that the coal strike would interfere with steel production. The strikes at Connellsville, Pa., were particularly unexpected by the operators, and presumably by the buyers of steel, and part of the heavy buying of steel in April was due to this influence. It is estimated that fully 6,000,000 tons of ingots were produced in April and May against about 4,900,000 tons in February and March. The superficial view is that production of steel was restricted in April and May by the coal strike. But in reality the speeding up of production

appears to have been for the manufacture of stock reserves.

It is true, of course, that there is heavy consumption of steel in certain lines, which were inactive last year, such as freight cars, automobiles, fabricated steel and rails. Freight car buying has been at about 15,000 cars a month since the first of the year, accounting for consumption of finished rolled steel at the rate of about 200,000 tons a month. Passenger automobiles have been produced at about 200,000 a month and trucks at a trifle over 20,000 a month. Including accessories, the automobile industry will account for about 150,000 net tons a month. Rails of all classes are being rolled at the rate of about 200,000 net tons a month. The four items total 700,000 net tons of finished rolled steel a month, leaving 2,000,000 tons to be accounted for otherwise.

Corrosion of Iron and Steel. Result of corrosion test of value only under carefully controlled conditions. Initial rate of corrosion is most important, since solution rates changes as equilibrium approaches. As rule, shorter time interval between solution changes nearer will test approach actual service conditions where corroding medium is changing continuously. If test carried out over long period of time, it will be found that weight losses are practically equal for all samples tested and that metal which in reality exhausted its solution first is erroneously deemed to have equal corrosion-resistance as metals actually far superior. Tank described for experiments on this subject. D. M. STRICKLAND, *Chem. Met. Eng.*, 6-21-22, 3000 w. CJW.

Manufacture of Iron and Steel Tubing. Author lists various processes by which iron and steel pipe and tubing are made, dividing them into the process in which a longitudinal seam is used and those without a longitudinal seam (seamless). There are ten such processes, two of them with modifications, so that the total rises to 14. The author describes each briefly and emphasizes those which are in common use in Germany, telling why such is the case. EWALD ROEBER, *Mechanical Engineering*, 5-22, 2600 w. MAH.

Iron Ore Concentration in Magnetic Log Washers. For concentrating crushed magnetite ores. Low-grade ore, on crushing to 150 mesh, is run through washers with magnetic poles in bottom which cause values to agglomerate and act as large particles easily separated from finer non-values; 25% ore concentrated to 65% iron and tailings contain only 1% magnetic iron. Extraction is better than 95%. Commercial machines now being installed. H. H. WADE, *Eng. & Min. Jour-Press*, 5-6-22, 3000 w. 7 Figs. APS.

Pure Iron Welding Wire. Has been proved that commercially pure iron wire of correct physical properties possesses every essential that could be advanced for suitable metal for welding mild steel plates, shapes, etc., by either oxy-acetylene or electric arc process. Chemical

uniformity of plate and wire should receive most careful consideration. Wire should not contain or tend to create gases, should be free from slag or slag-forming ingredients, should be chemically and physically uniform, and should embody ease of operation. C. A. McCUNE, *J. Am. Welding Soc.*, 6-22, 3000 w., 19 cuts. CJW.

Chrome-Molybdenum Steels. Really a short summary of the paper by C. N. DAVE read before the S. A. E. in June, 1921. It points out that, despite the many advantages then claimed for the metal in highly stressed parts when properly case-hardened by the special methods of the Studebaker Corp., that concern has now abandoned it for parts of that kind, substituting chrome-nickel as more easily (or at least more so commercially) hardened. *Automotive Industries*, 6-8-22, 650 w. MAH.

Heat Treatment of Chrome Steel for Ball Bearings. Discussion with numerous photomicrographs. HAAKON STYRI, *Amer. Soc. for Steel Treating*, 5-22, 3500 w. APS.

Tonnage of unfilled orders of the U. S. Steel Corporation. —(Iron Age.)

Chromium Magnet Steels. During the war, the need for tungsten in tool steels forced the elimination of this material in everything else, including magnet steels. This brought about the use of other alloys, and this article discusses the Reichsanstalt tests of chromium steel rods furnished by Krupp. These carried, respectively, 3%, 6% and 9% of chromium. The tests showed that steel with 1% and 9% were unsatisfactory but those with 2% to 6% of chromium indicated decreasing permanence with increasing hardening temperature and increasing coercive force. Oil quenching gave better results than water quenching. In cyclic heating tests for permanence the higher percentages of chromium showed up best, and similarly in shock tests. It would seem from these tests that an alloy with chromium at or around 6% would give great satisfaction as a magnet steel. *Automotive Industries*, 6-8-22, 1500 w. MAH.

Decreasing Weight of Magnets. A new type of magnet steel, a cobalt-chromium steel gives a total available energy of about 30,000 ergs per cc., which is three times that of ordinary permanent magnets (tungsten-chromium steel). Methods of hardening and testing of properties. Calculations for design. *Rare Material*, 5-22, 2200 w. APS.

Steel for Forge Welding. Principal factors—method of manufacture, chemical composition, fluxing quality, susceptibility to heat and welding temperature—affecting welding quality of steel are discussed and average results of 80 tests made on forge welds of hammer-welded pipe are compared with original material. It is stated that tests have demonstrated that both steel not over 0.15% carbon and minimum tensile strength of 47,000 lbs. per sq. in. and that not over 0.20% carbon and minimum tensile strength of 52,000 lbs. per sq. in. are satisfactory for forge welding of pipe lines, pen stocks, tank-car work and similar construction. Most important consideration to produce uniformly good results in forge welding of steel are suitable material, well-trained operators and adequate facilities for control of operations. F. N. SPETTER, *Mechanical Eng.*, 7-22, 1200 w. CJW.

Thermo-Electric Phenomena for Identifying Certain Steels. It is not possible to identify alloy steels with sufficient accuracy by means of the Brinell test, so Le Chatelier has worked out a method of testing steels by which the electromotive force produced by inserting the steel into an electric circuit may be measured. He has found with his apparatus that the same material always gives the same result when of the same composition, but will show a variation with very minute changes in composition. Hardening, on the other hand, has no effect on the reading. When this research is carried far enough, all steels may be classified and their readings listed. It will then be a simple matter to identify or prove the composition of any steel alloy by means of this device. *Automotive Industries*, 6-8-22, 800 w. MAH.

Uranium as a Steel Alloying Element. As uranium belongs in the group with molybdenum, vanadium and tungsten, all important metals in alloying steel, its use for the same purpose is being studied. It increases the hardness and hardening power of any metal to which it is added, having the peculiar property of doing this and other things alone, as contrasted with other alloying materials of which frequently two, or more must be used, one to produce one desired quality, another for another, etc. Uranium increases the ductility to a remarkable extent, so that uranium steels are preeminently adapted for uses demanding a low drawing temperature. A relatively small quantity of it will replace a fairly large quantity of tungsten and give equivalent results in certain special alloy steels. In the more complex alloy steels it intensifies the desirable properties without introducing any undesirable ones. Its chief drawback is cost, due primarily to the complex nature of the ores and their highly refractory nature; in fact, most of it is produced not for itself alone, but as a by-product in the production of radium or vanadium. *Automotive Industries*, 6-8-22, 1400 w. MAH.

Increase in Tensile Strength Due to Cold Drawing. It has been known for a long time that cold drawing increases the tensile strength of steel. Janitzky, metallurgist of the Illinois Steel Co., has attempted to classify all the records and data on the subject in an attempt to formulate a law. At the same time he has been able by plotting known data to produce a double parabolic curve and to derive a general equation for this. His deductions are interesting, but not conclusive because his data were incomplete. *Automotive Industries*, 6-8-22, 800 w. MAH.

Modern Methods of Making Leaf Springs. Machine formed springs are better than hand-formed product as result of new designs developed within past three or four years. Description of tempering and assembling, testing and inspecting. Excellent photographs. E. F. LAKE, *Iron Age*, 5-18-22, 1750 w. APS.

Breakage of Rolls on Sheet and Ton Mills. Part I. Discussion of characteristics of rolls used and methods of making and finishing them. Concave face when cold, but heat expansion causes straightening of face. Owing to differing rates of expansion of chilled surface and granular interior, rapid heating causes breakage, although torsional and bending stresses may contribute. Other causes are irregular operation, etc., all of which ultimately come back to improper heat conditions. W. H. MELANEY, *Blast Furnace & Steel Plant*, 5-22, 3000 w. APS.

New Five-Stand Cold-Rolling Strip Mill. This new 10-in. cold-rolling strip mill of the Greer Steel Co., Dover, Ohio, is unusual because it is a five-stand tandem design as compared with four-stand for ordinary cold-rolling practice. The predominating feature of the layout is the flexibility of the control, and this is due in large part to the fact that each mill stand has its own gear ratio. In addition, the drive was designed to take care of any reduction required, with spindles twice the usual length connecting pinion

between 56% and 63% copper, while high copper mixtures contain 87% to 100% copper. Physical properties of these mixtures are reported, and the microstructure of forgings discussed. O. T. RODER, *Forging-Heat Treating*, 6-22, 2000 w. CJW.

Cracks in Boiler Plates. Translation from Stahl und Eisen. Force influence figures developed by the new etching process worked out in the Krupp laboratories permit recognition of brittleness. Force influence bands showed up in new plates and were ascribed to cold working. From these tests and notched-impact tests authors conclude that manufacturers showed finish roll plates at as high a temperature as possible to increase toughness and reduce brittleness. Twenty-two excellent figures of specimens. B. STRAUSS and AD. FRV, *Forging & Heat Treatment*, 5-22, 3500 w. APS.

Arc Welding of Cast Iron. Discussion of carbon arc and metallic arc welding. Outline of general procedure recommended for doing metallic arc welding on cast iron parts. Ideal procedure

Millions of tons of pig iron produced each year since 1860, with estimated normal production represented by dotted line.—(L. P. Ayres, vice-president, Cleveland Trust Co.)

and rolls, and specially designed crab couplings. Further details of the installation and its products are given in the article. *Iron Age*, 5-11-22, 1700 w. MAH.

Brass Forging. Only successful method of forging brass consists in heating pill or slug in special furnace to 1250-1300° F. and then forging in this plastic condition. Small shapes are forged under 400,000 lbs. pressure, though larger pieces may be subjected to 400-600 tons. Not practical to forge shape over 4 in. in diameter or 3 lb. weight in 200-ton press. One press may produce 5,000 to 10,000 forgings per day. Die construction is fundamental consideration involved in forging brass. Design, workmanship and composition of steel are fundamentals in utility of such dies. High-speed tungsten steel should be used for actual section of forming die. Secondary parts may be made of cheaper steel. Intricacy of die determines its life. Low copper mixtures must contain

would result in welds having following characteristics: Good amalgamation of metals, secured by proper filler material and preheating; prevention of chilled metal at line of fusion or in weld, by same means; preheating will also accommodate expansion in casting and the combination will eliminate gas pockets and holes. Proper filler material can be obtained which will approximate characteristics of original casting and which will have same coefficient of expansion. Electrode material for welding cast iron by arc process should contain high carbon and silicon and low sulphur, manganese and phosphorus. A. R. ALLARD, *J. Am. Welding Soc.*, 1-22, 4000 w. CJW.

LUMBER·WOOD PRODUCTS

The Danger in High Prices

ACCORDING to the *Furniture Manufacturer and Artisan*, lumbermen are opposed to an advance in the price of their product because they know that the attainment of high prices means, in certain lines of manufacture, the substitution of some other fabricated product for theirs, and frequently this temporary substitution is made permanent.

It is pointed out that substitution for lumber is occurring in many channels of industry in spite of all efforts to counteract it. Steel, for example, has replaced lumber permanently, it is believed, in passenger cars, largely in freight cars, agricultural machinery, automobiles, barrels and casks, telegraph and telephone poles, fences, office furniture, business and industrial buildings and in many other ways. Concrete replaces lumber in a large variety of uses. Wood pulp and straw

board are used instead of lumber in boxes and other containers. The latest development of this kind is the radio, which is taking the place of the phonograph and even threatens the continued manufacture of pianos and other musical instruments, and the use of lumber in their cabinet work.

In many instances the price of lumber has had nothing to do with its disappearance from the industries referred to, but the substituted article has frequently been perfected while the article made of lumber has not been. In view of the present shortage of lumber, it is believed that consumption should be so adjusted to supply that nothing is wasted in manufacture, and also that no lumber should be produced beyond the wants of the public.

How Nature Produces Artistic Veneers.

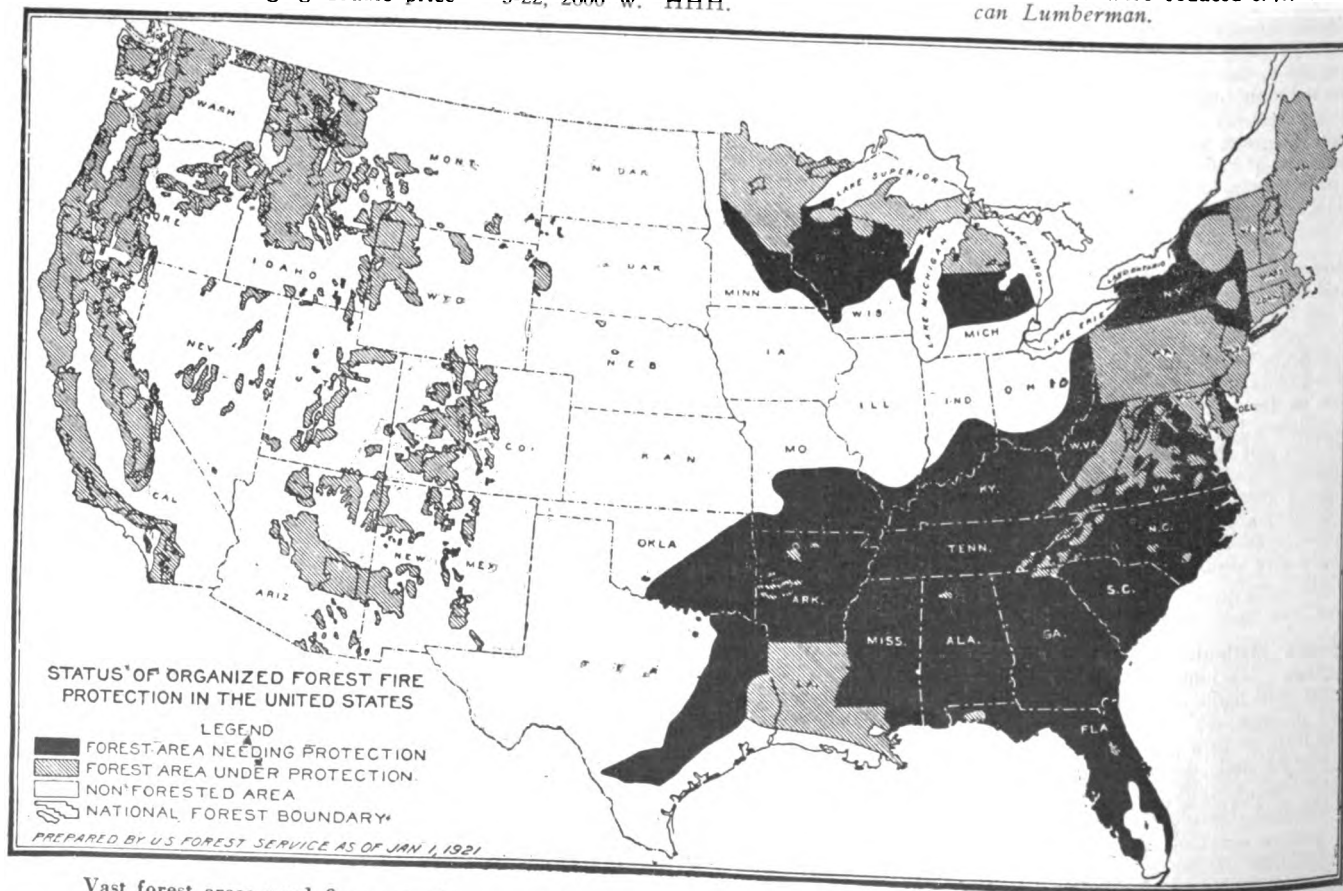

Beautiful figure found in some wood caused by vagaries of nature during growth of tree. Heavy winds and snowstorms responsible for some of markings. In other species of trees figure is produced when numerous small branches start to sprout and then cease growth in early life of tree. In some maples this rule is reversed—small projections on side of bark penetrate regular trunk growth and make irregular indentations, causing veneer cut from tree of this kind to be called bird's-eye maple. Another ornamentation in maple, birch and mahogany is formation of curls, often resulting in veneer bringing double price

of ordinary stock. Curls formed by filling in of spaces between forks of branches, fibers of layers growing in regular whirlpool fashion. ALEXANDER H. KOLBE, *Furniture Manufacturer and Artisan*, 6-22, 1800 w. HHH.

Timber Trade in France. Production of timber insufficient for needs of country. Two million cubic meters imported. United States may establish export trade with France more easily if endeavor is made to produce quarter-sawed material, in order to secure price that will counterbalance depressing effects of freight. ALPHONSE MATHEY, *Wood Turning*, 5-22, 2600 w. HHH.

English Styles in Furniture. Rugged individuality of early England evidenced in furniture of English origin. Most important periods: Tudor, Stuart, Dutch, Victorian. English styles most adaptable of foreign furniture styles to average American home. ROBERT RENNSSELAR CHAMBERLAIN, *Grand Rapids Furniture Record*, 5-22, 2500 w. HHH.

Skilled labor at Southern pine mills decreased 22% during 1921 and common labor decreased 29%, while wages of farm labor were reduced 37%.—*American Lumberman*.

Vast forest areas need fire protection, especially the regions rich in yellow pine in the South.—(*American Forestry*.)

Get this protection from your banker

Millions of bank depositors are now independent of mechanical devices, printed limitations, and other ingenious and bothersome methods of protection against check alteration.

These bank depositors are better protected — *more positively protected* — by checks with INSURANCE. They use Super-Safety insured checks furnished by their banks without charge. Whether written by pen and ink or mechanically, the Insurance protects them against loss through “raising.”

Ask your banker for these checks. If you cannot find one in your locality who has them, write us for the name of one nearby who will gladly accommodate you.

*\$1,000.00 of check insurance
against fraudulent alterations,
issued without charge,
covers each user against loss.*

**SUPER-SAFETY
Insured
BANK-CHECKS**

*Insured in the
HARTFORD
against loss through
fraudulent or
felonious alterations*

Machine-Tool Industry Back to Normal

A STEADY improvement is noticeable in the machine-tool industry. New orders are said to average between 20% and 25% of the peak business during war times. Six firms out of 77 recently canvassed stated that their business was more than 50% of peak business, while about 30 out of the 77 reported that they were doing a business that may be considered from one-third to one-half normal or better. Stocks have been materially reduced within the last two months. Nearly all the shops that were closed during the depression are now running to some extent and some of the largest report sales averaging 50% of what is considered normal.

According to *Machinery*, conditions in the electrical welding-machine field are practically normal. Shops devoted to electric welding on a jobbing basis are also well occupied. The electrical repair and motor-rebuilding business keeps shops running at full capacity, and the electrical tool business aver-

ages about 50% of normal. The tap and die business averages from 25% to 40% of capacity. The makers of special tools, jigs and fixtures average about 50% of a normal business, and a few of these shops are running full and even overtime. The vise business appears to be practically normal. In the ball and roller-bearing field the activity is 100%, due mainly to the heavy demands of the automobile industry. The drop-forging shops are fully occupied and those engaged in making automobile forgings have difficulty in meeting the demands. There is considerable demand for forgings for railroad cars, large orders for which have been placed by the roads during recent months. The foundry business is much better and prices of castings have increased to a level that is said to be satisfactory by the foundry operators; and the die-casting business is operating at about 75% of capacity.

New Gear Material. Known as "Condensite celoron." Claimed to be practically water, oil and grease proof. Tensile strength 8,000 to 10,000 lbs. per square inch. Compressive strength approximately 40,000 lbs. per square inch, laminæ horizontal, and 2,500 lbs. per square inch, laminæ vertical. Transverse strength is approximately 23,000 lbs. per square inch. Modulus of elasticity is approximately 1,550,000 lbs. on the average of 10 readings. Specific gravity 1.3 to 1.4. Coefficient of expansion .000017 per degree F. Gears should never be meshed with gears of similar material or with gears having uncut or badly worn teeth. Face of mating cut metal gear should be always equal to or wider than condensite celoron gear. *Canadian Machinery*, 6-8-22, 500 w. CJW.

New Tests in Fatigue of Metals. Description of research work at the University of Illinois, also of the machines used. In the so-called Farmer rotating beam machine, it has been found that the endurance limit (to alternate reversals of stress) is almost identical with the elastic limit. The latter, on the other hand, is not the permanent and unchangeable quality it has been thought to be. Other interesting points discovered in the research work are mentioned. *Automotive Industries*, 6-8-22, 1600 w. MAH.

Safety Gates. Surface landing gates at Cresson No. 9 mine, operated by electricity. Rack and pinion provided in place of usual sprocket and gear. Plan shown in cut. Gate opens in 6 seconds. Motor speed 900 r.p.m., so that 90 revolutions of motor are required. Three-quarter hp. motor sufficient for purpose. Electric circuit usually left open. Diagram of control for gate shown. *Coal Age*, 5-11-22, 400 w. CJW.

Metallic Packing. Discussion of durable metallic packing, which is self-lubricating, acid and alkali proof and successfully used at 800°F. New product is metallic gasket stuffed with rubber, flax, asbestos or other elastic materials, thus combining advantage of metallic gasket with resilience of rubber fibrous material. C. C. HALL, *Paper Mill*, 6-17-22, 750 w. CJW.

Machinery exports from Germany, United Kingdom, United States and France.—(U. S. Commerce Reports.)

Boiler-Room Instruments. Real value is not so much what instruments do as what executives do with instruments. Instrument records are likened to set of books in office, without whose aid keenest of executives would be unable to make any headway against constant encroachment of extravagant practice and inefficient methods. Have two distinct functions: Instantaneous reading indicated is of primary value to operating force; secondary value results from collection, interpretation and analysis of daily records, so that comprehensive record of operation is built up. Examples. D. HENDERSON, *Industrial Power*, 6-22, 1200 w. CJW.

Speeding Up Screw Thread Inspection by Optical Projection. A new tool for the inspection of screw threads in the Hartness screw thread comparator. Primarily, this is a device for supporting the screw or gear between a source of light and a projection microscope, with a special chart having tolerances indicated on it to receive the projected image. This arrangement makes it possible to see all the defects of the thread or tooth at a glance, and very largely magnified. Author describes the apparatus, its methods of use, general applications, and advantages. RALPH E. FLANDERS, *Automotive Industries*, 5-25-22, 3200 w. MAH.

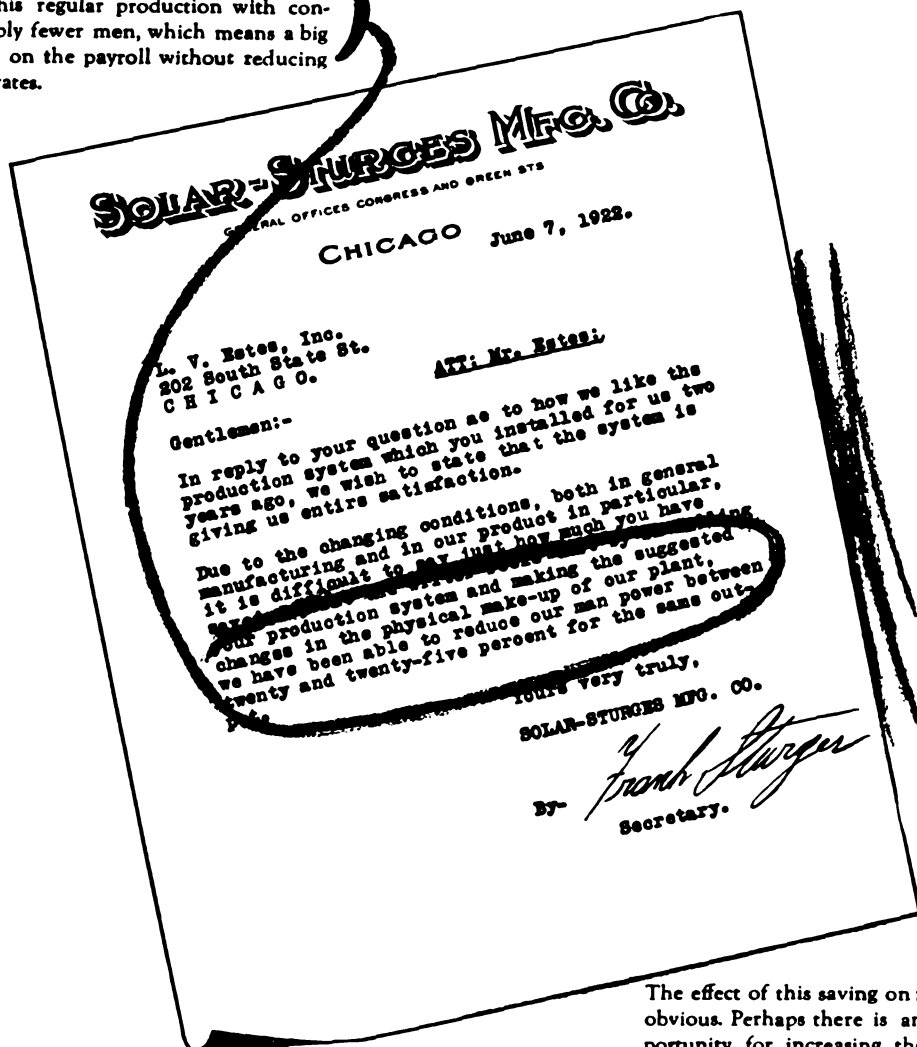

Emergency Closing Valve. This valve can be made to close either when steam pressure in supply pipe to turbine falls any predetermined amount below minimum allowable operating pressure or when pressure of lubricating oil becomes dangerously low or finally when turbine overspeeds. It insures instant automatic protection and its importance as secondary protection for large turbine units cannot be overemphasized. Operation illustrated and applications discussed. P. W. KNAUF, *Intern. Steam Engineer*, 6-22, 1200 w. CJW.

Prospect of Higher Prices for Lead

THAT gradual curtailment in the production of lead will result in higher prices is predicted by *Mining and Metallurgy*. It is pointed out that the lead production of the world has not kept pace with that of either copper or zinc, and today the possibility of producing copper is nearly double that of producing lead. And at the same time new uses, especially the storage battery and lead-encased cable, are making large demands on the world's output. Nearly half of the total production of lead is corroded to make paint and storage-battery oxides, the remainder being used for foil, shot, storage batteries, lead-encased cable, solder, sheet lead, babbitt, etc. A small amount is still used for pipe and plumbers' supplies. Ammunition accounts for a very small part of the total supply. Storage batteries, since the advent of auto-

mobile self-starters, rank next to paint in the use of lead. Radio receiving stations, each of which requires a storage battery, appear likely to rival motor cars in the amount of lead consumed.

Conditions today seem to justify Herbert Hoover's prophecy in 1909 to the effect that the prospect of higher prices for lead were more encouraging than for any other metal. It is pointed out that in spite of the present general business depression the lead industry is now more prosperous than any other non-ferrous metal. This is due partly to the fact that although the war increased the production of lead it did not increase the capacity for producing, whereas its effect on both copper and zinc was to increase enormously the production capacities.

Geology and Mining of Mica. Mica is the one indispensable dielectric. Increasing demand without prospects of a suitable substitute. Muscovite or "white" mica and phlogopite or "amber" mica are most important industrially. Long list of uses in electrical and other industries. Ground mica has also numerous uses. The commercially valuable ores occur only in pegmatites. Many minerals associated with mica may be valuable by-products such as gem varieties of beryl and zircon, rare radium and uranium minerals, pure feldspar, high grade apatite. Methods of mining, evaluation of the mineral and distribution. Preparation for market, grading. Necessity for improved methods of mining and preparation. J. VOLNEY LEWIS, *Eng. & Min. Jour.-Press*, 5-20-22, 7000 w. APS.

Mining Thin Seams. System described applicable to seams varying from 18 to 36 in. in thickness with tender friable coal, under comparatively heavy to very heavy cover, inclination of seam varying from level to five degrees. If roof is of clayey nature, best method would be longwall, advancing or retreating. Should be cut by mining machines and loaded by face conveyors, either belt or shaker. Seam should be laid out in panels, each panel to have its own split of air current. Method of timbering and size of timbers must be carefully selected. Other details given. G. A. M. REES, *Coal Age*, 6-15-22, 1800 w. CJW.

Latin America Resources. First of series of three articles describing mineral resources of Latin America and analyzing economic factors on which their development is dependent. Dearth of transportation facilities. Greatest source of wealth is Chilean nitrate industry. Life of field estimated at 200 years. Copper may surpass nitrate in few years. Gold and silver declining because of high costs. Tin is one country product Bolivia, which is second only to Malay States in production. Has all necessary group of minerals around which iron and steel industry centers but lacks coal. Iron countries are Brazil, Cuba, Chile,

Mexico and Venezuela. Only iron ores supplied to external commerce are from Chile. O. WILSON, *Chem. Met. Eng.*, 4-5-22, 2500 w. CJW.

Hydraulic Sand Packing. Brief discussion of proposition to fill in mines with sand, replacing ore taken out and providing place for sand removed from mine. Cost of hydraulic filling not appreciably higher than old hand-stowing of material in mine, while saving of time is considerable and less danger of mine fires. Little data on percentage of solids transported by water without danger of choking pipes. In this work 35% voids in volume of dry solids should be allowed. E. S. RIVETT, *Canadian Mining Jour.*, 4-28-22, 750 w. CJW.

Sulphur Dioxide Leaching Process. Discussion of process developed at Tucson, Ariz., to provide cheap and efficient method for treating so-called "porphyry" copper ores of Southwest, which generally contain both sulphide and nonsulphide copper minerals, mixed in such proportions that they can only be satisfactorily treated by method which will concurrently recover both forms of copper. Advantages of new method consists in: Plant is compact and not expensive, no installation difficulties, power requirements are light, operation simple and easily controlled, no delicate adjustments or critical points. Percolation difficulties common to leaching are entirely avoided. Perfect contact is assured between finest ore particles and reagent. Reagent is cheap and excellent utilization is attained. Process may therefore be extended to ores having much higher acid soluble gangue content than could be considered in ordinary sulphuric acid leaching practice. Details to be presented in Bureau of Mines Technical Paper 312. C. E. VAN BARNEVELD and E. S. LEAVER, *Reports of Investigations*, Bureau of Mines, No. 2350 (1922), 15 pp. CJW.

Methane Indicator. Burrell methane indicator, which measures amount of methane in mine atmosphere by means of graduated scale, contraction resulting from burning methane content of air being measured, has been formally approved by Bureau of Mines. Instructions for operation are given. L. C. ILSLEY, *Reports of Investigations*, No. 2367, Bureau of Mines, 3 pp. CJW.

Mechanical Loaders. Practical difficulty today consists in not being able to keep machine in continuous operation due to removal of loaded cars. Section of mine must be prepared for exclusive use of shovel. Locomotive should be kept in attendance on this machine exclusively. This must take sufficient number of cars into entry to clean up working face so that when last car is loaded they can be removed, leaving track clear for loader to move to new point. Plan is illustrated. Coal should be sheared before shooting. Loader permits of uniform and systematic advances, simplification of main haulage, ventilation, pumping, etc. and in new development, rapid increase in daily output and attainment of ultimate output in comparatively short time. Higher recovery is possible because of quicker working. W. R. CALVERLEY, *Coal Age*, 6-15-22, 1500 w. CJW.

Accidents and Diseases in Coal-Mining. Based on study in Utah. Increase year by year shown by following table:

	1917	1918	1919	1920
Deaths	17	24	28	32
Permanent total disability	0	0	0	2
Permanent partial disability	11	20	16	25
Temporary disability:				
28 days and over	111	165	192	206
14 to 28 days	139	150	273	199
4 to 14 days	509	446	545	505
Under 4 days	778	838	1,124	1,155

Total temporary disability

1,537 1,599 2,134 2,065
Days lost from accidents increased from 18,820 in 1917-18 to 26,641 in 1920-21. Production loss has increased from 101,816 to 140,931 tons in same period. Loss to employees likewise increased from \$45,507 to \$63,370, while total cost of accidents has risen from \$741,808 to \$881,027. A. L. MURRAY, *Coal Trade Bul.*, 5-16-22, 1000 w. CJW.

Many of the coal mines today are better ventilated than are numerous of the city office buildings—*Steam Shovel and Dredge Mag.*

What Can You Afford?

Can you afford to speculate in your endeavor to win the things you can't afford?

Can you afford to overlook the safety and absolute certainty of accumulating wealth by means of *well advised* investments?

There is no knack about making money; wealth is a reward of knowledge. Money-making is rarely accidental; fortunes are built deliberately.

Few men or organizations can give reliable advice on investments. Decisions affecting the buying, selling or shifting of investment holdings should logically come only from a trained specialist in economics—just as medicine prescriptions should come only from an accredited physician.

The sole business of the Brookmire organization is to help investors realize the utmost earning capacity of every dollar. Results have been conspicuously successful.

The cost of the service, because of the thousands who use it, is negligible. Write for Pamphlet DD, which tells you exactly why you can't afford to invest without the advice of the Brookmire Economic Service.

Planning, editing, gathering news, articles and information, how to buy and use art and engravings, etc. It contains 80 and sometimes 96 pages of information.

HOUSE ORGAN HEADQUARTERS, 187 Montague Street, Brooklyn, N. Y.

OILS·PETROLEUM

No Decline in Oil Prices Expected

ACCORDING to the *Magazine of Wall Street*, the outstanding feature of the oil industry is the paradoxical situation with regard to rate of production, supplies in storage waiting for market, and crude and refined oil prices. It is pointed out that "when production and storage supplies of any industry fall below normal the industry might be supposed to be 'statistically' strong; when they rise above normal the analysts of the trade might be expected to shake their heads solemnly and forecast a decline in prices." But the reverse appears to be true of the oil industry today. The production of crude oil in the United States has for a number of years been going forward in record-breaking proportions, and there is not at the present time any indication of a let-up. Over 1,450,000 barrels were produced per day early in June, while the average daily imports of 435,000 barrels from Mex-

ico increased this supply to nearly 1,900,000 barrels. Meanwhile the consumption rate was only about 1,400,000 barrels.

But in spite of the fact that an excess production of about 500,000 barrels a day is accumulating, the price of oil has steadily increased. In the opinion of the writer, the explanation of this paradox lies in the fact that in former times whenever demoralization threatened, the dominant factors in the industry used to go out among the smaller independents and buy up their refined products. But about two years ago this policy was discarded in favor of one which called for the purchasing of crude instead of refined. So today prices are likely to stay up in spite of the large supplies of refined and crude oil on hand, because these supplies are in the hands of corporations equipped to hold them. There is almost no opportunity for the small or badly managed company to succeed.

Surface Tension of Petroleum. Value of specific tension increases with specific gravity. Small quantity of fatty acids and wax present does not appear to influence values. High boiling fractions and products of high viscosity tend to raise surface tension of lighter petroleum products such as gasoline and

naphtha. Values decrease with increase in temperature, approximating 0.05 dynes per sq. cm. per degree F. Surface tension in conjunction with other tests may aid in determining lubricating and other values of oil. C. K. FRANCIS and H. T. BENNETT, *J. Ind. Eng. Chem.*, 7-22, 2500 w. CJW.

Analytical Distillation of Petroleum

Analytical distillation of petroleum is commonly made to determine range of boiling points or to separate oil into fractions for detailed examination of both. This bulletin describes apparatus and methods used by Bureau of Mines for routine examination of crude and lubricating oil and describes also apparatus developed for certain types of research. Some of the methods for studying fractions separated are described also for dehydrating emulsified oils which is often necessary preliminary to analytical distillation. E. W. DEAN and others, *Bulletin 207*, Bureau of Mines 1922, 82 pp. CJW.

Filters for Lubricating Systems. Two best methods are: Oil is continuously passed through filters or separators and all foreign material removed before oil is delivered to bearings and partial filtration system, in which portion of oil is continuously by-passed through filters and is automatically returned to system after being cleaned. Latter used where amount of impurities is very small and permits use of smaller and less expensive equipment. Oil should come out bright and clear. W. F. OSBORNE, *Power*, 6-13-22, 1000 w. CJW.

Lubrication Engineer. Two great general problems today are fuels and lubrication. Great deal of confusion in latter case. Introduction of mineral oils started complications. Simplification of practice has been mainly brought about by lubrication engineer. Primarily interested in all economies that can be effected through use of lubricants. Must know mechanics and oils. Must organize entire matter of handling petroleum products so there will be no waste of products in storage or in use. Also interested in reclaiming used products. W. M. F. PARISH, *Intern. Steam Engineer*, 6-22, 2000 w. CJW.

Tapping a dome into which gas and oil are forced by the hydraulic pressure beneath.—(*Magazine of Wall Street*.)

Common Sense

Millions are spent yearly on advertising.

The fundamental purpose of advertising is to mold public opinion and educate the prospective buyer.

But of late, progressive manufacturers have come to recognize that it is even of greater importance to properly mold the opinion of labor. Where this is being done a spirit of GOODWILL and COÖPERATION follows.

Owing to the varied types of workers, and the mistrust existing between Employer and Employee, the "selling" of Management to its men cannot be effectively done through the printed word or other usual advertising methods.

The unique method which we have developed is thoroughly successful and profitable.

*"The Worker's viewpoint is the
Most neglected Factor in Industry"*

RUBBER • PLASTICS

Tennis Shoes Popular in Tropics

THAT a rapidly expanding market for rubber footwear is to be found in the tropics is indicated by recent export figures, which show that at the present time exports of rubber footwear amount to one-third of the value of exports of leather shoes. During the month of May the export of canvas shoes with rubber soles amounted to 232,952 pairs, worth \$192,939; rubber boots were shipped to the extent of 25,408 pairs, worth \$73,664; rubber shoes came to 42,291 pairs, worth \$45,449, and rubber soles and heels amounted to \$58,615.

Shoes of the tennis type constitute the bulk of these exports. The Philippine Islands were the best customers for these shoes, taking 64,000 pairs during the month of May. They were also one of our best customers for rubber soles and

heels. Next in the list is Cuba, with 45,000 pairs of tennis shoes and the largest purchase of rubber soles and heels. Mexico and other tropical countries are also large buyers. England is third on the list with 35,000 pairs, of which it is believed many were reshipped to tropical countries.

According to *American Shoemaking*, these tropical wearers favor the tennis shoe because it is comfortable to the foot from the first moment of its wear. There is no uncertainty about its fit. The price, even with a considerable profit added is reasonable. The tropical wearers' verdict is so unmistakable that it should offer encouragement to rubber manufacturers in this country who specialize in the production of what youngsters call "sneakers."

Rubber Containing Magnesium Carbonate. Light magnesium carbonate is light inorganic filler for rubber which has heretofore received little attention from American rubber technologists. Data is given showing that this material behaves as typical reinforcing pigment, increasing tensile strength, stiffness and resilient energy capacity of rubber with which it is compounded. Comparison between physical properties of this rubber with those containing zinc oxide, gas black, china clay and barium sulfate indicate that magnesium carbonate is exceeded in reinforcing properties only by gas black. Principal disadvantage is property of imparting high permanent set to vulcanized product, attributable to

definite crystalline or nonamorphous character of particles. Believed that application of principles of colloidal chemistry to conditions of commercial process will enable this material to be prepared in amorphous form, which will make it much more valuable as rubber compounding material, by reducing objectionable permanent set and enhancing tensile strength and toughness of rubber compounded with it. H. W. GREIDER, *J. Ind. Eng. Chem.*, 5-22, 8000 w. CJW.

Onazote is a new form of rubber sponge, three times lighter than cork, a non-conductor of heat and cold and impermeable to water.—*Tractor World*.

Polish Rubber Industry and Its Prospects for Development. An interesting account of the conditions existing in the Polish rubber industry at the present time, the demands for various sorts of rubber goods, the export outlook. *Rubber Age*, 4-10-22, 1500 w. IG.

Temperatures and Friction Losses Determined by Tire Research. This is a summary of results on a number of articles on tire research work. Writer points out herein that tire problems divide naturally into two kinds: mechanical in which the tire user is largely concerned, and chemical in which the manufacturer is more largely concerned, even the automotive engineer not being greatly interested in the latter. *Automotive Industries*, 6-8-22, 500 w. MAH.

Temperature of Pneumatic Truck Tires. Since the use of pneumatic tires for trucks has become general, so that the very large truck sizes are now manufactured in large numbers, much interest has been displayed in the matter of heating. Of course all tires heat, but the big question has been do they heat in proportion to their sizes or internal air pressures. On either score truck tires could be expected to attain very high temperatures. This paper delivered before the S. A. E. describes methods used, results obtained, and other things incident to the general experiments. Over a period of several months, the highest temperature of any part of a 40x8 tire did not exceed 215° in a room which averaged 90°, so the highest temperature reached did not exceed room or atmospheric temperature by more than 135°, which is relatively cool. In another table of such differences, this figure is given as 96°, and that for a 42x9 tire as 123° maximum. F. O. ELLENWOOD. *Automotive Industries*, 6-8-22, 3200 w. MAH.

Rubber in Radio Sets. Hard rubber is unexcelled in the construction of various parts of radio sets. Great extent of industry opens up new and extensive uses for rubber. Soft rubber has but little use in radio work. *India Rubber World*, 5-1-22, 500 w. IG.

Gypsum. Part V. Covers chemical composition and use. JOSEPH K. COSTELLO, *Building Materials*, 5-22, 3000 w. CS.

Domestic inventory, production and shipments of pneumatic cord and fabric tire casings and inner tubes during the calendar year 1921. This chart of vital tire statistics was prepared by the Tire Manufacturers' Division of The Rubber Association of America, Inc., based on figures submitted by tire and tube manufacturers, as indicated in the small square at the left. In December the number of manufacturers making returns was more than 1.42 times greater on casings and 1.36 times greater on tubes than in January.—(*India Rubber World*.)

The Building Boom

Authoritative Books for Executives

THE greatest building boom ever known in the United States is now in full swing. Coming after the world's greatest war, with the consequent disturbance of ordinary trends of trade and thought, together with disturbed labor and transportation conditions, many projects present new problems. No one executive can hope to have intimate knowledge of all there is to know about building in all its phases. Fortunately, however, there is available a large number of authoritative books, covering all departments of building and construction, and giving many money-saving ideas. Each is the product of an expert on the subject covered, and is worthy of a prominent place in every building executive's reference library. Below are the titles of only a few books which *The Industrial Digest* recommends. They can be shipped promptly, upon receipt of the price specified, postpaid—books cannot be sent on approval. If you do not find below the book you want, describe your needs in a letter to the Book Department.

PRINCIPLES OF ARCHITECTURAL DESIGN, by Percy L. Marks.

In his previous work, "Principles of Planning," the author dealt with the principles underlying planning; in this later volume he shows the steps to be taken to produce elevations suitable for any given plan. Many of the full-page plates are from designs of leading architects. 165 full-page plates and many other illustrations. \$4.50, postpaid.

HEATING AND VENTILATION, by John R. Allen and J. H. Walker.

The causes of heat loss from buildings, different methods of heating, the use of hot air and steam equipment, systems, piping, temperature control, fan systems, air washing, and central heating are each taken up logically and explained; advantages and disadvantages are discussed clearly. 332 pp., illus. \$3.59, postpaid.

COLLECTED PAPERS ON ACOUSTICS, by Wallace C. Sabine.

The book deals with reverberation, its variation with variation in pitch, melody and the origin of the musical scale, effects of air currents and of temperature, sense of loudness, the correction of acoustical difficulties, theatre acoustics, building materials and musical pitch absorption by audiences, architectural acous-

tics, the insulation of sound, whispering galleries. 279 pp. \$4.00, postpaid.

CONCRETE WORK, by William K. Hatt and Walter C. Voss.

The reading of blueprints, calculation of quantities, estimates of cost, selection and inspection of materials, equipment, organization of gang, staking out, excavating form work measuring, mixing and depositing concrete, and protection of work are all clearly and practically treated. 451 pp., 224 figs. and 20 full-page plates. \$4.00, postpaid.

MASONRY STRUCTURES, by Frederick P. Spaulding.

The principles of masonry structures are clearly and simply illustrated, various types being analyzed. 404 pp., 129 figs. \$3.50, postpaid.

BUILDING CONSTRUCTION AND SUPERINTENDENCE (3 vols.), by F. E. Kidder.

The first volume presents the latest and best modern practice in masonry construction. The second deals with the carpenter's work. Volume three, on trussed roofs and roof trusses, describes nearly every type of roof construction commonly met with, computing loads, drawing stress diagrams, etc. \$17.50, postpaid. Volumes sold singly: No. 1, \$7.00; No. 2, \$7.00; No. 3, \$3.50.

MATERIALS OF CONSTRUCTION, by A. P. Mills.

To the architect and engineer the "Materials of Construction" will be found of decided interest. The consideration of each material or class of materials is prepared by a discussion of its ordinary application in engineering construction, followed by a study of its manufacture or natural occurrence, and concluded by a discussion of its physical and mechanical properties in their relation to its uses. 484 pp. \$4.00, postpaid.

LAW OF ARCHITECTURE AND BUILDING, by Clinton H. Blake.

Invaluable for the architect, engineer, owner, contractor and all who have to do with building construction. A consideration of the mutual rights, duties and liabilities of architect, owner and contractor, with appendices and forms. 352 pp. \$3.00, postpaid.

ARCHITECTURAL COMPOSITION, by J. B. Robinson.

The chapters cover the standard of taste, what is architecture, entity, individuality, similarity, subordination, analysis of buildings, primary and secondary masses, details, horizontal division, proportion, contrast, practical applications, flexibility of types, comparison and criticism. 234 pp. 170 illus. \$3.50, postpaid.

TEXTILES

Prospects for Cotton Crop Excellent

ACCORDING to the recent forecast of the Department of Agriculture, the cotton crop this year will be larger than in 1921. The yield, estimated on the condition of the crop on June 25, was forecast at 11,065,000 bales, which compares with a production of 7,953,641 bales last year, 13,439,603 bales in 1920, 11,420,763 bales in 1919 and 12,040,552 bales in 1918.

The condition of the crop on June 25 was reported as being 71.2% of normal, an improvement over the report issued the month previous, when it was placed at 69.6%. The condition compares with 69.2% on June 25, 1921, and with the ten-year June 25 average of 76.9%. It forecasts a yield per acre of about 151.9 pounds, compared with an acre yield of 124.5 pounds last year.

The acreage devoted to cotton this year was placed by the Department at 34,852,000 acres, an increase of 10% over the

area planted in cotton last year. This increased acreage is regarded by the Department of Agriculture as a partial return to normal conditions, resulting from better prices and low stocks. Increases are shown in all States except South Carolina and Georgia. It is reported that the carry-over of stocks from last year has been cut in half, and that surplus cotton has practically disappeared.

The acreage devoted to cotton for the present season, as compared with the revised figures for previous years, together with the acreage harvested is as follows:

	Acreage Sown	Acreage Harvested		Acreage Sown	Acreage Harvested
1922.....	34,852,000	1916.....	36,052,000	34,985,000
1921.....	26,519,000	31,470,000	1915.....	32,107,000	31,412,000
1920.....	37,043,000	35,878,000	1914.....	37,406,000	36,832,000
1919.....	35,133,000	33,566,000	1913.....	37,458,000	37,089,000
1918.....	37,207,000	36,008,000	1912.....	34,766,000	34,283,000
1917.....	34,925,000	33,841,000	1911.....	36,681,000	36,045,000

Yarn Breakage. In cotton warp dyeing, spongy or soft balling with overlapping ends should be returned for rewinding. Careful handling at boiling out box is absolutely necessary. Drums beneath boiling out liquor should be examined regularly for cracks or roughness, likewise squeeze rolls. Slack warps dangerous, especially in dyehouses which double warps after boiling out. Majority of breaks will naturally take place in actual dyeing. Care necessary here to keep all parts in perfect condition. Main cause of yarn breakage at dryer is warp running back and winding around steam dry cans. Constant supervision and careful handling all along line will eliminate much of this expensive fault. L. W. SIDEBOTTOM, *Am. Dyestuff Reporter*, 7-3-22, 1200 w. CJW.

Warp Yarn Mercerizing. Process more mechanical than chemical, since mercerizing under tension is only application of process in practice. Description

of processing warps for knitting trade. 40° Tw. is lowest concentration of caustic soda effective. Yarn in contact for two minutes. Caustic removed by washing on counter-current principle in four compartments, and then passing through 3% sulphuric acid at normal temperature. To obtain best luster, only combed yarns should be used, as fibers lie parallel. Singeing or gassing yarn prior to mercerizing adds considerably to resultant luster. This luster due to surface reflecting, brought about by swelling action of caustic soda and untwisting of fiber while under tension. LAWRENCE A. STEAD, *Southern Textile Bul.*, 2000 w. CJW.

Woolen and Worsted Cloth Finishing. Continued article. This installment discusses dewing, steaming and brushing, cutting, cropping and shearing machines. Original should be read. *Textile American*, 6-22, 7-22, 4000 w. CJW.

Specialty Yarns. These include changes in color, direction of twist and strength. These are comparatively level and regular in appearance, but there is also yarn spun to show thick and thin places at irregular intervals, "nep" yarns, with neps as an attraction, all of which are single yarns. Numerous effect yarns can be produced on comparatively simple doubling machines by utilizing expansion and contraction of threads of equal or unequal counts, according to amount and direction of twist. Examples are given. J. H. KERSHAW, *Textile American*, 6-22, 1200 w. CJW.

Dyeing Pulled Wool. Goods containing pulled wool to which particles of silk adhered gave trouble with two-bath process. Problem solved by bleaching with potassium permanganate, sodium bisulphite and sulphuric acid. Goods were then well rinsed and dyed as usual. G. E. TEMPLETON, *Am. Dyestuff Reporter*, 7-3-22, 300 w. CJW.

Percentage of active worsted and woolen spindles and of active wool looms, to June, 1922.—(Textile World.)

Keep Pace With Evolution

DARWIN declared the human race was merely an evolution of the monkey tribe. Some people agree with him. Others do not.

But there is no denying that even within the memory of most of us, there has been considerable of an evolution in the human mode of living. And today, this evolution is buzzing along faster than ever.

There has never been a time when conditions changed so rapidly—when life bettered itself so consistently. New comforts and conveniences are coming in all the time. And the rapidity with which they are invented and put before us vitally affects us all.

To take advantage of these things, you must keep yourself informed. You must know not only what they are, but also how much they cost and where and how to get them.

The only way you can know this is to be a regular reader of the advertisements.

Advertisements tell of all that the world is doing to make you more comfortable, your work easier, your methods better, your clothing and food problems less irksome. They tell you how you can save time—and effort—and money in the selection of the things that make life worth while.

Advertisements are interesting, instructive and highly profitable to you.

Dyeing Acetyl Silk. General characteristics of present-day artificial silks. For direct cotton dyes, acetyl groups may be split off by caustic alkali; process does not affect luster of silk but fiber becomes more like other cellulose silks in physical and chemical properties. Basic dyes have direct affinity for acetate silk and no mordanting is necessary. Salt has remarkable effect in increasing absorption of dye by fiber. Discussion of colors produced by various dyestuffs. W. E. SANDERSON, *Am. Dyestuff Reporter*, 7-3-22, 1500 w. CJW.

American and Indian cotton crops and yields per acre since 1894.—(*Manchester Guardian Commercial*.)

Dyeing Artificial Silk. First of series of articles on dyeing mixtures containing artificial silk. Sulphide colors are suitable to dyeing artificial silk. These are fast to "acid cross-dyeing." The silk may be dyed after manner of cotton, providing certain precautions are taken, such as avoidance of heat, prolonged immersion and mechanical stress. List of dyes with relation to cotton and wool. General discussion of acetyl and viscose silks. GEORGE EMMONS, *Silk*, 6-22, 1500 w. CJW.

Theories of Dyeing. Three theories, chemical, mechanical and solid solution, briefly discussed. No one entirely satisfactory and all are far from expressing real truth. Do show how very complex are processes involved in dyeing textiles. *Canadian Dyer and Color User*, 6-22, 1000 w. CJW.

Formic Acid and Dyeing. Formic acid called acid of future. European dye-houses are using it more than American dyers. Formic acid much less harmful in its action upon textile fabrics than oil of vitriol or niter cake and nevertheless it exhausts dye bath satisfactorily. Users of formic acid state that more level dyeing, better penetration, brighter and bloomier shades are obtained, and that raw stock dyed with it spins and weaves better. In mordanting it exhausts bath well and at same time hurts wool but little. Formic acid is

now being manufactured to meet demand which must increase as time goes on. Mills will do well to investigate thoroughly possibilities of formic acid. GEORGE H. JOHNSON, *Am. Dyestuff Reporter*, 7-3-22, 2000 w. CJW.

Two-Color Dyeing. Brief report of discovery of A. G. Green of new class of dyes which will enable dyer to give permanent color to artificial silk. The "ionamines" dye silk yellow and cotton blue in the same bath. *Canadian Dyer and Color User*, 6-22, 750 w. CJW.

Control in Piece Dyeing. In dyeing piece goods varying temperatures of the dye liquor are responsible for many irregularities in finished shade. Discussion of modern mechanical devices combining time and temperature control. N. INCOLL, *Am. Dyestuff Reporter*, 7-3-22, 1500 w. CJW.

Job Dyehouse. General description of equipment for various classes of work and various operations, such as scouring, bleaching, dyeing and finishing. A. T. BRAINERD, *Am. Dyestuff Reporter*, 5-22-22, 3000 w. CJW.

Fastness of Colors. Recommendations of German commission for series of tests of fastness of color, covering following points: Washing and boiling test for fastness of colored cottons; washing test for fastness of colored wools. The following data are established for this test: Colored wool against white wool, and white cotton. Rinsing tests in cold water for colored cotton and wool. Rubbing test for cotton and wool. Ironing tests. Testing fastness with sulfur. Perspiration tests for colored cotton and for dyed wool. *Canadian Dyer and Color User*, 6-22, 1200 w. CJW.

Direct Blacks on Cotton. Direct blacks used in dyeing of jet blacks, grays of different shades and fastness, ground for aniline blacks, compound shades, as matching color covering in calico printing, and as ground to be discharged in calico printing. Discussion of these uses. Plant for jet blacks with substantive colors illustrated, and advantages enumerated. R. SANSONE, *Am. Dyestuff Reporter*, 6-5-22, 2000 w. CJW.

Thin Boiling Starch. Better weaving warps made by using thin boiling starch than those sized with thick boiling or crude starches. Various methods used to modify ordinary cornstarch into thin boiling variety. Distafor used with some success, also chloride of lime; addition of dextrin to ordinary mixing will also thin starch, but these processes weaken size and produce variable results. Long boiling, without use of chemicals, under easy control and produces uniform thin starch. *Textile American*, 5-22, 1200 w. HHH.

A Hundred Millions for Good Roads Next Year

THE continuation of Federal aid for road construction has resulted in the recent authorization of an appropriation of almost \$50,000,000 for distribution among the several States during the fiscal year beginning July 1, 1922. Under the conditions of the aid each State must match the sum allotted it. It is estimated that \$100,000,000 will thus be spent throughout the country during the coming fiscal year.

The Post Office appropriation bill recently signed by President Harding authorizes an appropriation of \$65,000,000 for road building during the year beginning July 1, 1923, and \$75,000,000 for the succeeding fiscal year. The conditions are the same for all three years and with an equal amount appropriated by the States will bring the total amount expended, if the States expend equal sums, to \$380,000,000.

It is estimated that these appropriations will result in the construction of 71,000 miles of roads—nearly 40% of the estimated 80,000 miles of good roads included in the system of Federal aid roads now being planned.

The apportionment to be made to the various States for the fiscal year which began July 1 is approximately as follows:

Alabama	\$1,035,614	Nebraska	1,034,400
Arizona	702,188	Nevada	635,400
Arkansas	836,095	New Hampshire	243,000
California	1,641,399	New Jersey	628,000
Colorado	894,117	New Mexico	793,000
Connecticut	320,599	New York	2,464,000
Delaware	243,750	North Carolina	1,134,000
Florida	591,217	North Dakota	776,000
Georgia	1,331,972	Ohio	1,880,000
Idaho	625,691	Oklahoma	1,108,000
Illinois	2,164,187	Oregon	788,000
Indiana	1,305,904	Pennsylvania	2,267,000
Iowa	1,401,915	Rhode Island	147,000
Kansas	1,401,521	South Carolina	700,000
Kentucky	944,786	South Dakota	800,000
Louisiana	664,660	Tennessee	1,064,000
Maine	463,440	Texas	2,990,000
Maryland	427,086	Utah	566,000
Massachusetts	730,784	Vermont	247,000
Michigan	1,499,688	Virginia	972,000
Minnesota	1,415,731	Washington	755,000
Mississippi	863,271	West Virginia	534,000
Missouri	1,632,086	Wisconsin	1,260,000
Montana	1,031,257	Wyoming	620,000

Total.....\$48,750,000

Highway Transportation Research and Automotive Progress. Author says that the industry must form the habit of thinking of the vehicle always in relation to the highway. Such a method of thinking would give the highway its proper position in the perspective. Traffic surveys have been sporadic, but now are being improved in character and usefulness. According to these surveys March and April are the months of average traffic. Surveys generally show trucks to be overloaded. This is bad for the roads, especially when a considerable portion of the trucks are of very large capacity. Fuel consumption is closely related to road design and construction; also poor roads make for higher fuel consumption. Author takes up in some detail Maryland, Connecticut, California and other surveys. Other subjects treated include road costs, store door deliveries, container cars and others. H. S. FAIRBANK, *Automotive Industries*, 6-8-22, 10,300 w. MAH.

Jack-Knife Crane Solves Problem of Restricted Space. This is a description of a novel crane which was designed and built for the Government commission supervising the Mississippi-Warrior River service. Much of this work necessitated the handling of many small packages and others up to ten tons between a vessel and a freight shed built close to the water's edge. To operate successfully, it had in addition to be of

Variation in cost per mile, in thousands of dollars, on four types of pavement. The Bureau of Public Roads of the U. S. Department of Agriculture recently reported as completed since 1916, 11,017 miles of Federal-aid road and gives mileage of each type and average cost per mile. Figures based on large volume of work and are most recent, giving average costs for the whole United States. Figures cover entire cost of construction, excluding large bridges; in a few cases cost of engineering is not included. Figures are based on entire period of operation of Federal-aid, but major portion of work has been done since 1918.—(Concrete.)

Freight car supply and car loadings (thousands of cars daily).—(United Business Service.)

such a nature as not to interfere with the vessel's rigging, boat stanchions, or other apparatus attached to vessel or dock. The floating form of crane which the Robins Conveying Belt Co. designed and built for this unusual situation is called the jack-knife type and is erected on a floating power-driven barge, one of the old barges propelled by producer gas being used. The article describes barge, crane and its operation. *Engineering News-Record*, 4-20-22, 750 w. MAH.

Distribution of Wheel Load on Pavement Sections. Results of tests on Bates experimental road to indicate effect of traffic. Illustrated with typical curves. H. F. CLEMMER and C. A. HOENSTHALER, *Highway Engineer & Contractor*, 6-22, 2000 w. CS.

History of Conveying Belts. Development of the use of belts in conveying coal, coke, ore, crushed rock and vessel loading is traced historically. T. ROBINS, *India Rubber World*, 5-1-22, 2400 w. IG.

The continent of Asia, nearly six times the size of the United States, has only one-fourth the railway mileage of this country.—*Tractor World*.

Operation of Single Phase Interurban Lines. Details of operation of Chicago Lake Shore and South Bend Railway are given. C. N. WILCOXON, *Electric Traction*, 6-2-21, 6,000 w. IG.

The Industrial Direct

Exports, Imports

(From page 1200)

Machinery

ALTHOUGH there is at present no market for American machinery in Belgium, owing to the fact that considerable stocks of American machinery have accumulated there, appreciation of American equipment, even at higher prices, is indicated by the fact that at the recent commercial fair one of the best known Belgian manufacturers sold no lathes whatever, while several purchasers were found by representatives of American manufacturers. Orders of machinery for restoration purposes appear to have been concluded. Some shop construction is reported, however, in the vicinity of Brussels, and a certain amount of buying for replacements and development is being done by producers of light mechanics. It is believed that moderate price concessions would somewhat extend sales of American shop equipment in this district.

Australia presents an expanding market for machinery, as shown by the latest Australian statistics. A large increase is noticeable in the value and percentage of machinery imports from the United States in 1921 as compared with pre-war figures. In 1913 American manufacturers furnished machinery valued at \$1,245,516, or 29% of the total, as against \$3,884,396, or 43%, in the fiscal year ending June 30, 1921. Great Britain and the United States practically monopolize the Australian machinery market.

Oils, Petroleum

THERE is a good market for lubricating and paint oils in the Swansea district of Wales, which is a center for steel works, tinplate works, sheet works, tube works, copper works and nickel works. These industries consume large quantities of lubricants. The district also has several ports where lubricating oils are purchased for vessels. Considerable quantities of paint oils and paints are also consumed annually for repair work on vessels.

The oils consumed in this market are chiefly of British manufacture, though considerable quantities of American oils are used, and the latter is in good repute.

Paper

THE market for stationery in Arabia is steadily increasing.

At present it is supplied principally by Great Britain, India, Italy and Austria. The United States has just entered this market and operates mainly through jobbers in England. The city of Aden is the principal market in this district. Imports of stationery into Aden amounted to 22,768 lbs. in 1919-1920, and 22,768 lbs. in 1920-21 compared with only 3,595 lbs. in 1913-14. It is believed that the figures for 1921-1922 will show a further increase, due, in great measure, to the attention being paid to education.

Rubber

A VERY good market for rubber goods is to be found in China. The value of the total imports of rubber manufactures in China in 1920 was \$2,075,067, of which approximately 42% came from Japan and 30% from the United States. The general distributing centers for rubber goods are Shanghai, Tientsin, and Darien.

Due to the prolonged rainy season a good market for galoshes exists in Damascus. It is estimated that about 10,000 pairs were sold last season. Russian galoshes formerly ruled the market because of the resistance they offered to the wear of the bad streets, but the closing of the Russian source of supply has brought the American article into prominence.

Textiles

THERE is a demand for high-grade cotton goods at present in Venezuela. Imports are supplied chiefly by the United States and England. Other countries in which very

good markets for cotton piece goods may be found are Rumania, China, and India. Official trade statistics for the Indian fiscal year, April, 1921, to March, 1922, indicate that India's imports of cotton piece goods have reached their lowest level and that from now on improvement may be expected.

New Charting Plan

(From page 1282)

cannot be stored up and used out of stock; there is no time lag between its production and use."

A glance at the curves on the chart on page 1282 shows considerable variations throughout the year. The curves for the years 1919 and 1921 can be considered as characteristically portraying central station load curves and the effect of the longer summer days when less electricity is used for lighting.

The trend of these curves can be readily seen—a decline as the summer months approach and a corresponding rise toward the end of the year. The steep declines in the last weeks of November and December are due to the shutting down of the factories for the holidays.

The 1920 curve, however, is not normal, as it drops below normal as midsummer approaches; beginning in November, it drops to the end of the year. The whole curve for 1920 shows clearly that an abnormal condition prevailed throughout that year.

The curve for 1922 is the most interesting, for, rising sharply during the second week in January, the trend is almost horizontal across the chart, contrary to what would be expected under normal conditions. As with the 1919 and 1921 curves, we would expect the 1922 curve to drop about the middle of January, but instead it fluctuates, with the trend horizontal. Due to longer daylight there had been a proportionate reduction in the use of electricity for lighting since the middle of January, 1922, but for a few weeks prior to the end of March, shops and factories of all kinds were using more electricity for power purposes, because of the addition of new machinery and longer working hours. This means "the employment of more men and, consequently, the output of a greater volume of manufactured product for the whole community."

From this graph, measured in kilowatt hours, the conclusion may be drawn that business is improving in Cleveland. The kilowatt hour records facts and in all probabilities it will not be long before this plan of gauging the trend of business conditions by the kilowatt hour, will be adopted in all the large cities.

Business in Brazil

(From page 1280)

Perhaps they will be able to gather a few useful hints from the following, published by the Brazilian Ministry of Agriculture, Industry and Commerce under the title "Practical Suggestions to Exporters:"

"If American exporters to Brazil suffer by contrast with their rivals in other countries, this is due chiefly to the recent entry of the United States into the field of international trade. An imperfect acquaintance with Brazilian business houses, commercial traditions and customs, as well as with the more general conditions, tastes and preferences of the Brazilian people, are at the bottom of the major part of the misunderstanding which has arisen in the past.

"Another factor, less important *per se* than for the effect which it has had in creating a general impression, are the inevitable cases of abused confidence arising from attempts of unscrupulous exporters to exploit a distant market, or of similar importers to take advantage of conditions unknown to their suppliers on the other side.

"The proof of the truth of the above statements is the well-known fact that American houses of high standing which have had sustained relations with Brazilian houses of the

same class, are at no disadvantage as compared with rivals.

"The important factors in foreign trade are the price and quality of the goods; tastes and preferences of the foreign market; and the terms of payment. It is probably true that the American exports is disposed to place greater emphasis on the price and quality of his goods as his strong selling points than to make concessions to the preferences of his customers or terms most agreeable or usual in Brazil.

"It should be carefully noted, however, that the last two factors often outweigh the others in the Brazilian importer's mind, when he is making a decision between competitors. The tastes of the Brazilian market is a matter to be studied in detail in the case of each commodity, and general statements cannot be made.

"Regarding the last factor, terms of payment, it may be worth while to point out certain facts pertaining to trade with Brazil.

"The important variations in practice between American exporters and certain European rivals have to do with credit terms, disposition of documents, and adjustment of claims.

"Credit, when extended to Brazilian houses by American exporters is usually on a basis of 60 to 90 days sight draft, or 120 days date draft, and these terms are satisfactory.

"The American exporter, however, has been much more reluctant to grant credit than were his European competitors, especially the Germans. The latter, on a basis of intimate acquaintance with the market, would accept a very much lower rating than American houses care to do. With the coming of American banks to Brazil in recent years, the handicap of insufficient information no longer exists, and the most reliable and accurate information is now available regarding all important firms of Brazil.

"Furthermore, a large part of European business with Brazil before the war was done on open account, usually with a limit of six months, which was even extended to one year in the case of some articles, such as textiles, pianos and machinery. In one Brazilian center it is said that quite one half of Germany's business was done on this basis. American exporters do little business on open account as yet.

"The primary consideration with Brazilian houses in asking for credit is the length of time necessary to inspect and clear the goods from the Custom House. This may require from 30 to 60 days after the arrival of the goods in Rio. Rarely do Brazilian houses ask for a longer time than is necessary for clearance and arranging the goods in stock, but credit for this period is considered indispensable, and general it will be difficult to trade on any other basis.

"The following quotation from a report by an American Consul reveals another side of the credit situation in Brazil: 'Brazilian houses which do an immense business and have no need to solicit credit still continue to do so out of force of habit. It is a custom inherited from the past. While the practice of American exporters of arranging their export lists to permit a graduated series of discounts, varying with the length of the credit terms, is unquestionably beginning to influence many Brazilian importers to meet their terms, the old conservative practice is deeply rooted.'

"Another point upon which many Brazilian houses are sensitive is the disposition made of documents. European houses make a practice of sending them direct to the customer, and not attaching them to the draft. The importer usually insists on seeing the goods before accepting the draft, and provision for this should be made by the exporter, either by authorization or by sending documents direct to the purchaser.

"Interest rates for the period of the draft are usually included in the price rather than collected direct.

"Commercial letters of credit, as provided for by the American banks, are becoming increasingly popular with the large Brazilian merchants as a means of financing imports when sufficient inducements are offered by American exporters.

"Finally, emphasis should be laid upon the exact compliance with instructions given to the exporter by the Brazilian importer regarding measurements, weights, quality, packing and invoices. Upon the exporter's faithful attention to these particulars often depends the salability of the goods in

Brazil, and a large percent of the complaints registered against American business has to do with this point. Articles 'just as good,' or even better than those ordered, and which the domestic buyer in the United States would be glad to have sent him without the delay of correspondence, are likely to be entirely useless in Brazil."

The Business Weathervane

(From page 1263)

The Unfavorable Factors Are: 1. Competitive bidding for labor in the building trades. This competition has enormously increased prices for labor in these trades and is causing a construction cost which might require deflation when conditions ease off and rentals lower. 2. The continued coal and textile strikes. The voluntary idleness of men is a great burden on the income of the country and a situation that ought not to exist. Despite the strike, coal production is increasing yet the heavy toll of these strikes should lead to an effort to find some better method for the settlement of labor disputes. 3. The failure of the bankers' conference in Paris to reach terms upon which a German loan could be floated brings a set back in the economic situation which must be recorded as an unfavorable symptom the world over. 4. The continued unsettlement of financial and business conditions in Europe is fast becoming serious, and a crash is unavoidable unless there is a springing to the necessity of the situation and some plain talk on the part of the nations most deeply interested. Among them our country must be included. 5. Pending tariff and bonus legislation which tend to restrain business because responsible for uncertainties. 6. A rise in the prices of finished product, together with the slight increase in the cost of living.

In the opinion of **Dun's Review**, the month of June was noteworthy for the preponderance of advances in **Dun's** weekly lists of wholesale commodity quotations, and the rise in the July 1 index number had been plainly foreshadowed. The net result was an increase of 2.2%, following a moderate upturn in the two immediately preceding months, and the general price level is now higher than at any previous time since April 1, last year. Examination of the record shows that the downward price reaction which began in the early summer of 1920 culminated about a year later, and the subsequent trend has been almost steadily toward recovery.

What Constitutes a "Spread"?

(From page 1277)

or otherwise, sold in the stores which support the organization has been estimated as probably less than 5% of the entire volume of goods handled by such stores, thus proving conclusively that the department stores are not dependent on imported merchandise for their livelihood."

The Dry Goods Association states that it is opposed to the proposed tariff because its rates have not been constructed in a scientific, non-partisan, non-political manner; because it carries higher rates on most finished products than a sound protective principle requires; because it will tend to raise prices to the consumer; because it will tend to restrict imports necessary to the international commerce of the United States and in so doing will damage the interests of all those whose exportable surplus the international price has a vital and direct influence, such as the farmer, the cotton grower, the producer of metals, the exporting manufacturer.

The Saving Grace

as applied to magazines, means the retention of all issues which may be worth something later on. We submit that *each* copy of the *Industrial Digest* is worth saving because of the more than five hundred digests of important articles which it contains. The Annual Cumulative Index which will be sent without charge to all subscribers will make this valuable data instantly available, *provided* the copies are filed for reference.

And for this purpose we are prepared to furnish neat, strong, handsome binders, done in black cloth with gold lettering, and capable of holding a year's copies, at the moderate rate of two dollars each.

Order now and keep your copies in good condition.

INDUSTRIAL DIGEST

25 West 45th Street

New York City

A Master Key to the News of Business

OUT of all the flood of information that pours in on you through newspapers, trade papers, magazines and other sources, how are you to sort out the pertinent facts that bear on your business? Wouldn't a master key to the news of business be worth (literally) its weight in gold to you?

THE INDUSTRIAL DIGEST is precisely such a service. Out of all the news of the daily press, the trade and business press and all other sources, it selects, verifies, evaluates and arranges the business facts of importance and sets them forth digested and indexed—and interestingly presented.

THE INDUSTRIAL DIGEST presents the business fortnight in perspective. It offers the major executive in every field of business the opportunity to keep himself acquainted, with a minimum of attention, with important events in his own industry and in other fields of business as they bear on his own.

IT costs tens of thousands of dollars a year to prepare THE INDUSTRIAL DIGEST. But the subscription price to each executive is only five dollars a year.

This coupon will bring the service to you once every two weeks for one year.

THE INDUSTRIAL DIGEST,
25 West 45th St.,
New York City.

Please send your fortnightly survey of American industry and commerce to me for one year. I enclose five dollars, check or money order.

INDUSTRIAL CALENDAR

Secretaries of Associations are invited to send us the dates of their conventions as early as possible so that their conventions may be properly listed below. When especially requested by Association Secretaries, we will send dates and other available notices concerning meetings of other associations.

- July 25-28. *National Retail Tea & Coffee Merchants Assn.*, Hotel Statler, Detroit, Mich. (R. M. Heizer, Secretary, 1201 Cornell Ave., Indianapolis, Ind.)
- July 26. *Western Pme Manufacturers' Association*, Portland, Ore.
- July 27-28. *National Lumber Manufacturers' Association*, Portland, Ore.
- July 31. *Wall Paper Manufacturers' Assn. of the United States*, Hotel Commodore, New York.
- Aug. 7-11. *Universal Craftsmen Council of Engineers*, Cleveland, O. (Thomas H. Jones, Sec., 33 Linden Ave., Cherrydale, Va.)
- Aug. 7-25. *National Merchandise Fair*, Grand Central Palace, New York. (Lew Hahn, Director, 200 Fifth Ave.)
- Aug. 9-10. *National Association of Window Glass Mfrs.*, Atlantic City, N. J.
- Aug. 12-14. *International Monumental Granite Producers' Assn.*, St. Cloud, Minn.
- Aug. 13-19. *American Ceramic Society*, summer excursion, New York State and Canada.
- Aug. 15-17. *Memorial Craftsmen of America*, Springfield, Mass. (T. E. Cassidy, Secretary.)
- Aug. 22-25. *International Assn. of Municipal Electricians*, New Bedford, Mass.
- Aug. 23-25. *American Association of Railroad Superintendents*, Kansas City, Mo. (J. Rothschild, 400 Union Station, St. Louis, Mo.)
- Aug. 24-25. *Canadian Gas Association*, Hamilton, Ont. (G. W. Allen, Secretary, 19 Toronto, St., Toronto, Ont.)
- Aug. 28-Sept. 2. *Graphic Arts Exposition*, Mechanics Building, Boston.
- Aug. 28-Sept. 2. *National Safety Council*, Detroit, Mich. (S. J. Williams, Sec., 168 N. Michigan Ave., Chicago, Ill.)
- Sept. 1-7. *Natural Gas and Petroleum Association of Canada*, Niagara Falls, N. Y. (S. A. Morse, Secretary, 48½ Market Square, Chatham, Ont.)
- Sept. 4-9. *American Chemical Society*, Pittsburgh, Pa. Divisional meetings will be held at Carnegie Institute of Technology and general meetings at Carnegie Music Hall.
- Sept. 4-9. *Gas and Fuel Section of the American Chemical Society*, Pittsburgh, Pa. (Dr. R. S. McBride, Secretary, Colorado Bldg., Washington, D.C.)
- Sept. 7-9. *New York State Coal Merchants' Association*, Richfield Springs, N. Y. (G. W. F. Woodside, Secretary, Arkay Bldg., Albany, N. Y.)
- Sept. 11-15. *Association of Iron and Steel Electrical Engineers*, Cleveland. (J. F. Kelly, Secretary, Empire Bldg., Pittsburgh.)
- Sept. 11-16. *Bakery Equipment and Material Exposition*, Municipal Pier, Chicago, Ill. (B. M. Warner, Secretary, Conway Bldg., Chicago, Ill.)
- Sept. 11-16. *National Exposition of Chemical Industries*, Grand Central Palace, New York. (F. W. Payne, Sec., Grand Central Palace, New York.)
- Sept. 11-16. *International Assn. Printing House Craftsmen*, Boston.
- Sept. 12-14. *Retail Bakers of America*, Chicago. (J. M. Hartley, Secretary, 10 S. La Salle St., Chicago.)
- Sept. 12-15. *American Bakers Assn.*, Chicago. (H. E. Barnard, Secretary, 1135 Fulliton Ave., Chicago, Ill.)
- Sept. 19-22. *Pacific Coast Gas Assn.*, Santa Barbara, Cal. (W. M. Henderson, Secretary, 445 Sutter St., San Francisco, Cal.)
- Sept. 21-23. *American Electrochemists Society*, Hotel Windsor, Montreal, Canada.
- Sept. 23-27. *National Assn. of Cost Accountants*, Atlantic City, N. J.
- Sept. 23-30. *New York Closed Car Show*, Grand Central Palace, New York.
- Sept. 25-29. *National Association Retail Druggists*, Detroit, Mich. (S. C. Henry, Secretary, 168 N. Mich Blvd., Chicago, Ill.)
- Sept. 25-30. *National Association Advertising Specialty Mfrs.*, Chicago, Ill. (B. Blackwood, Secretary, 208 S. LaSalle St., Chicago, Ill.)

Foreign Events

- August. *International Fair*, Hamburg, Germany.
- Aug. *Second Sample Fair*, Lublyana (Leibach), Yugoslavia.
- Aug. 12-20. *Third Annual Sample Fair*, Liberee (Reichenberg), Czechoslovakia.
- Aug. 27-Sept. 2. *Autumn Fair*, Leipzig, Germany.
- September. *Sociedad Rural Argentina*, Buenos Aires, Argentina.
- Sept.-Nov. *Engineers Congress*, Rio de Janeiro, Brazil.
- Sept. 7-Nov. 12. *International Exposition (centennial)*, Rio de Janeiro, Brazil.
- Sept. 15. *International Fair*, Bandoeng (Java).
- Sept. 15-20. *Automobile Show*, The Hague, Holland.
- Sept. 18-23. *Second Annual Metting of the International Chamber of Commerce*, Rome, Italy.
- Sept. 21. *Textile Fair*, Hamburg, Germany.
- Sept. 22-25. *Fifth International Fur Fair*, Lucerne, Switzerland.
- Sept. 25-Oct. 3. *Automobile Show at the Kaiserdamm Hall*, Berlin, Germany.
- Oct. 1-15. *General International*, Lyons.
- Oct. 4-15. *Automobile Show*, Grand Palais, Paris, France.
- Oct. 12-23. *International Commercial Vehicle Exhibition* at Olympia, London, England.

Handles More Tons Per Dollar

OPERATING cost of new model guaranteed not to exceed one cent per ton of coal handled.

Was ever a portable conveyor so amazingly economical as this New Scoop Conveyor?

As owners of preceding models heartily testify, the Scoop Conveyor has always been singularly economical to operate.

But owners of the new models insist that the amazing economy of the new model has never been equaled or approached before, even by the fine Scoop Conveyor forerunners.

In fact, owners of the new conveyors are unanimous in proclaiming the 1922 model Scoop Conveyor the greatest conveyor ever produced.

What Makes the Wheels Go 'Round?
The Power Problem Analyzed

Nationally Priced

Davis Pressure Regulator prices are stabilized. You can buy them anywhere at the prices quoted. Order through your dealer or direct from the factory. State whether screwed or flanged ends are wanted and specify initial and delivery pressures. Give information regarding any special condition or service.

The following prices are net, F.O.B. Chicago and apply to both the diaphragm and the piston type.

Size	Price
3/4 in.	\$22.50
1	25.00
1 1/4	27.50
1 1/2	30.00
2	35.00
2 1/2	42.50
3	50.00
4	70.00

The famous Davis P & W Pressure Regulator for use on any low pressure steam or vacuum system of steam heating where the delivery pressure to be maintained does not exceed five pounds.

THE Davis organization is always looking for improvements—always experimenting.

But—in adopting new principles the Davis organization is always *conservative*.

And this conservative policy has been proved out by almost a half-century of success. Think what that means!

To get the Davis O. K. a principle must be more than sensational, more than what appears to be good; it must have survived the severest practical tests over a telling period.

When you install Davis Valve Specialties you know you are getting tried principles backed by construction and workmanship that has passed the Davis O. K. —a mighty safe guide in buying valve specialties.

Try the Davis Regulator. It has no springs to fail or diaphragms to cause trouble and shorten its life. Utilizing the positive principle of the simple balanced scale, it maintains a constant reduced pressure regardless of fluctuations in the higher pressure. Sizes 1/2 to 14 inches.

Or the Davis Back Pressure Valve. It operates noiselessly and never sticks or binds—maintains a positive back pressure for heating, drying, cooking and other purposes. Sizes 2 to 30 inches.

Or the Davis Float Valve. It has a single seat with a renewable composition disc that makes it close tight, preventing leakage. Sizes 1/2 to 14 inches.

Or the other Davis Valve Specialties listed below, which will be described for you in detail by the G. M. Davis Regulator Co., 409 Milwaukee Ave., Chicago.

Water Control Valve
Non-Return Valve
Exhaust Relief Valve
Balanced Valve

Stop and Check Valve
Pump Governor
Emergency Stop Valve
Flow Regulator

Fluid Level Controller
Water Relief Valve
Steam Trap
Pump Stop Valve

You Must Trap Your Steam or Waste It

**—and who wants to waste steam at
present prices of coal?**

WITH coal costing as high as \$13 a ton—and often hard to get at any price—it is far cheaper to put in enough Steam Traps Sarco to stop loss of steam through condensation than to stand the alternative of big waste at the coal pile. Steam Trap Sarco puts the whole question of proper trapping vs. waste of coal on an entirely new basis—

It pays for itself at points where a big trap wouldn't be justified

You can put in *three* Sarcos for the cost of just *one* bucket or floor trap—thus for the same expenditure saving *three times as much steam* and therefore *three times as much coal*.

Because it costs only one-third as much, a Sarco will quickly pay for itself at points where the expense of an old-style trap wouldn't be justified. And after paying for itself, every ounce of steam and every shovelful of coal it saves is all clear gain—for the upkeep is practically zero. No complicated mechanism to get out of order or require constant adjustment and attention. It has only one moving part.

Sarco is more dependable and efficient than old-style traps. It operates automatically—on a simple yet extremely sensitive and responsive system of liquid expansion and contraction. So positive in action that not an ounce of live steam can escape from one year's end to the other.

Drains off all condensate as fast as it forms—and immediately returns it to the hot well—while still *hot*, thus requiring less coal to convert it back into steam. And never any water (condensate) left in the pipes to freeze overnight or over Sunday.

30 Days' Trial

We are ready to let Sarco demonstrate its superiority and economy right in your own plant by sending you one on 30 days' free trial without a cent in advance. If for any reason you aren't satisfied with its performance, if it doesn't prove that it quickly pays for itself through the coal it saves, then you can return it and it won't cost you a cent.

Made in sizes $\frac{3}{8}$ in. to 3 in. for any given pressure up to 200 lbs. Booklet No. F-18 and full particulars about our free trial on request.

Taking The Question Mark Out Of Business Records

Picturize Business Conditions with Rand Colored Signals

No waiting to search records. A glance shows it all. Multi-colored transparent signals plainly PICTURIZE current conditions peculiar to any business. A composite picture gives a complete summary of your records in surprising detail. Ask for particulars—get the vitally interesting facts.

MILLIONS of dollars are annually invested in that little commercial hook—the Question Mark. In almost any office you can hear high-priced executives asking questions, but getting unsatisfactory answers.

What is the reason? ?

Information is incomplete!—the records don't show!!—data is difficult to find!!!—someone is absent and the others "don't know"!!!!

Excuses are legion, but who pays for it all?

A big Eastern Corporation had a tidy sum invested in question marks. Doubt and guesswork had proved expensive. Then they installed—

RAND Visible Index Systems

After one year the General Manager wrote—"I am surprised at the results realized with Rand. Visible features enable a positive control of stock. Invested capital is reduced to a minimum. Rand Equipment has been a paying investment."

Many of our customers were doubters at the start; today they are boosters because of direct savings effected in the handling of their business records.

*If you want results instead of question marks—
if you want dividends—profits—instead of never-
ending costs, send a sample of your present
records and let us prove what RAND Methods
can do for you. Put your problem squarely up
to us. You may think it "different," but we enjoy
solving the difficult jobs. Write today—there's
no obligation.*

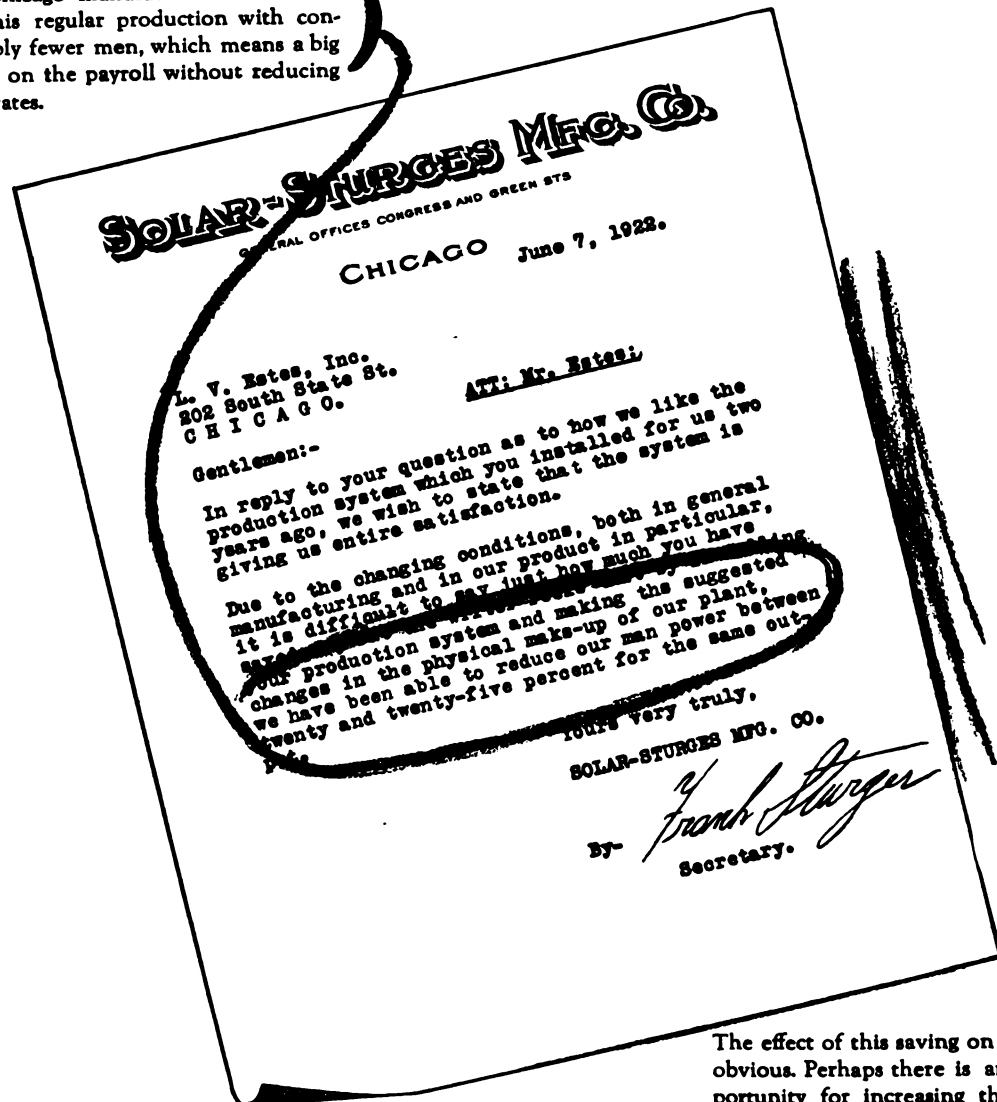

Rand Company, Inc.
308 Rand Building
North Tonawanda, N. Y.

*Originators and World's Largest Manufacturers
of Visible Index Equipment*

Cut Labor Costs 20% *Without Cutting Wages*

This Chicago manufacturer now maintains his regular production with considerably fewer men, which means a big saving on the payroll without reducing wage rates.

The effect of this saving on net profits is obvious. Perhaps there is an equal opportunity for increasing the profits of your business.

Consultation on Request

A PART OF OUR SERVICE is to send an engineer to your plant to examine conditions that exist and consult with you as to the value of changes that might be made. This service is *without charge or obligation* to you. Just write or phone that you would like to have it.

CHICAGO

The Business Weathervane

A Summary of Expert Opinion

The **Brookmire Economic Service** points out that the disturbing factors which have been retarding business developments recently are apt to overshadow the significance found in the favorable aspect of fundamentals, and adds that "First—Easy credit conditions with expanding industrial loans, shown in a rising volume of rediscounts. Second—A rising volume of production in basic commodities, notably iron and steel, lumber, paper and oil, and though steel ingot production declined in June, steel orders registered a notable increase. Production of textiles and coal have been hampered by strikes, but with

an early strike settlement in sight, a rising volume of production may be at once expected. Third—As a consequence of rising production a rapid absorption of workers in industry is noted throughout the country. Fourth—Failures are stabilizing and taking on the proportions and normal mortalities from month to month. Fifth—A gradually rising price level in wholesale commodities. Bradstreet's index number showed an advance as of July 1 of 1.7% over June, standing on July 1 at 12,1096. Sixth—A much better crop generally than last year is now likely at prices which cannot but improve the purchasing power of farmers. More active industry will materially increase the buying power of industrial workers. Good railroad earnings will affect favorably the ability to buy of railroad companies. Further, the probability of better returns from industrial investment, through sustained or increased dividends, give promise of generally increased purchasing power this fall."

The **United Business Service** points out that the financial aspect for the fall and winter is very favorable on account of the following items: "1. The reduction of money rates to normal levels. 2. An advance of 12 points in the average of 40 bonds. 3. An advance of about 20 points in the average

of 50 stocks. 4. Hundreds of millions given to industry through new financing. 5. Banks in strongest position in history. On the mercantile and industrial side inventories have been readjusted, surplus stocks reduced in all lines, unsound enterprises weeded out, costs of production reduced and wages readjusted. Railroad and industrial earnings have risen, business confidence has been restored, and commodity prices have risen about two-thirds the distance ordinarily covered in pre-war cycles."

(New York World)

Keeping him under.

The **Magazine of Wall Street** believes that industrial corporations, including public utilities and railroads, may expect a constantly improving financial condition due to the following factors: "1. Liquidation of high-priced inventories. 2. Reduction of bank loans. 3. Lowering of interest rates. 4. Lower cost of materials. 5. Increased efficiency of labor. 6. Greater stability of markets. The combination of the above factors in connection with the larger amount of incoming business has contrived to lower the per unit cost. Reduction of overhead expenses accomplished in this way is responsible for the improvements in earning-power."

Forbes Magazine agrees with other leaders of economic thought that "the spirit of enterprise is distinctly reviving. Forceful entrepreneurs have regained confidence in the outlook. What is equally important, they can also obtain very

readily and on reasonable terms all the capital necessary for whatever plans and projects they have in mind. Bankers everywhere are seeking out safe borrowers and trying to induce them to borrow substantial amounts. And as the general opinion is that we have now reached a reasonable price level as well as a reasonable wage level, it is coming to be felt that the time is about ripe for branching out, at least in the home market."

Dun's says that the general rate of business is slower.

Strikes Likely to Increase Prices

REPORTS from every quarter agree that the rail and coal strikes are beginning to make themselves felt uncomfortably. Fundamental conditions for fall business were excellent in the early spring but even though both strikes should end this month there will still be two distinct checks which will partially nullify those prospects. The first is an unmistakable fuel shortage and the second is the probability of the worst traffic tieup with which this country has ever been faced.

In addition, if the coal and rail strikes are not settled promptly there is every possibility of an increase in unemployment, a shortage of commodities and a sharp rise in prices.

The loss of production and of distribution occasioned by any strike can never be recovered. An excellent example is the recent situation in Russia where for a time the entire population quit work. Even there, however, prices mounted so rapidly that the few concerns that succeeded in selling commodities which they had on hand were made very wealthy in terms of money. The tendency is the same in every strike. The more people involved in the strike and the longer its duration, the greater is the tendency toward an increase in commodity prices. Conditions were favorable to such a price increase in the early part of the year and with the bituminous coal miners out for four months and the railway shopmen out for one month there can hardly be any question that commodity prices will show an advance this fall and winter. The longer the strike the greater will be the advance.

This fact is of tremendous importance to everyone in business. In the first place such an advance will, if carried to any lengths, make necessary a readjustment in wages which up to this time have been steadily dropping in every industry. In the second place it will have a direct effect on retail sales and indirectly a great influence on production. Consequently it is important to estimate as closely as possible when the strikes will end.

How Long Will They Last?

THE prospects of terminating the rail strike (which is treated at some length in the following pages) may be considered fairly good when the following facts are taken into consideration. The Government is apparently insistent

upon an immediate settlement. The rail executives have been, according to best reports, considering a request to President Harding that he permit them two to four weeks in which to meet strike conditions and place transportation on a normal basis. They believe that this can be done.

The strikers, through their chief spokesman, have made the claim that they can win the fight in four or five weeks. It is natural in disagreements of this sort for both sides to overestimate the length of time required for a settlement and thus it would seem fairly probable that within the next two or three weeks, or possibly a great deal sooner, the rail strike will have been terminated. The seniority point seems to be the only one which is still in dispute and some compromise will not doubt be effected on this score.

Coal Strike Still Deadlocked

WHEN the coal strike is considered prospects of an immediate conclusion are not so good, however. First of all there seems to be a general agreement among Administration officials to settle the rail strike first, on the theory that even were the coal miners back at work the roads could not handle any more fuel at the present time. In the second place the miners show no signs of a desire to return to work and their ranks are holding firm to a remarkable extent. Perhaps never before has union solidarity been so well exemplified, as in the present mine strike. If the purpose of the operators was to break up the United Mine Workers they have probably failed.

In the third place public opinion is not yet thoroughly awakened to the seriousness of the situation. It is a curious fact that an anthracite shortage will cause public interest to awaken very quickly whereas the much more important effects of a bituminous shortage fail to create any great demand for a settlement for a long time. The public will have to see factories shut down and feel the pinch of reduced payrolls before any general clamor will be made for a settlement.

In the fourth place there does not seem to be any inclination on the operators' part to concede anything whatsoever. Should the strike be settled at present it would mean a defeat for the operators with the miners returning to work on a more favorable wage basis than was originally anticipated. The operators have apparently determined to "fight it out on this line if it takes all summer" and unless the Government

(St. Louis Globe-Democrat)

A last lump to feed the hungry boilers.

in Perspective

steps in it will probably take all summer and most of the fall.

The creation of a Federal commission with control over the production of coal or control over conditions governing the production of coal seems to be but a matter of time. The President has advised Senator Borah that he would back any legislation which would prevent a recurrence of the present situation. The two factors in government control will probably be the creation of a wage board after the character of the Railway Labor Board and some method of price control based in all probability upon the Hoover method of interstate control with individual State responsibility.

The priority orders in transportation which went into effect on July 25 have already affected unfavorably those industries which were placed far down on the list. One of the unfortunate features in this respect is the fact that orders to many mills are being cancelled on account of inability to meet delivery dates.

Crops Promise Well

THE crop situation has been greatly improved recently by favorable weather. At the present time prospects are good for the current yield in cotton and in most of the

cereals. The financial condition of our farmers was greatly improved by the higher prices obtained for the last of the 1921 yield. They were able to greatly reduce indebtedness at the banks and to pay for fertilizer and equipment with which to improve 1922 results. Yet with the incoming crops larger than had been expected it will be difficult to maintain present prices unless Europe is a large buyer. The demand from abroad will certainly be less than normal and possibly not enough to take up our surplus. Thus the favorable effect of a good crop may be to some extent offset by a softening in price.

The Peak Reached in Certain Industries

THE business recovery has been most complete in the automobile and building industries and apparently in these two lines the peak has been reached. The oil industry is feeling the result of large stocks on hand and there have been recent cuts in the price of petroleum products. The steel industry is showing a steady improvement hampered only by the recent coal situation. It is not generally believed that the interference will be of long duration or that it will have serious consequences to the steel industry.

(Brooklyn Daily Eagle)

A Month of the Rail Strike

ON July 1, 400,000 shopmen left their jobs in protest against the \$60,000,000 wage cut ordered by the Railway Labor Board. For a time it appeared likely that the same number of maintenance-of-way employees would also strike but the agreement of the Labor Board to arbitrate their wages prevented the walkout. The shopmen have demanded that the wage reduction be set aside, that rules affecting overtime pay should be modified and that the practice of "farming out" repair work should be entirely abolished. President Harding's attempt to settle the strike have up to this writing proved unsuccessful, although an early termination is hoped for by the Administration. The railroad executives have made strenuous efforts to keep traffic moving and have been successful in many cases. For example, the New York Central system recently made a public statement with figures of car loadings showing a steady improvement in operations. The Pennsylvania system also reported a continued improvement throughout the entire road and gave figures showing the daily increase in the numbers of shopmen returning to work.

In order to keep freight shipments moving the railroads have had to promise permanent jobs to the new men that are being hired. This of course will force the railroads to retain the new men in place of the shopmen who walked out and consequently the strikers have forfeited all seniority rights. The Administration hopes to have the railroads modify their decision on seniority, but practically all executives to date have strongly insisted that the men forfeited all such rights when they left the road and that it would be difficult if not impossible in case of future strikes to secure men outside if the railroad's promise to the men hired in this instance were broken.

In fact there has been a statement made that many of the executives and officials of the roads would themselves go on strike by resigning their positions if the strikers were taken back with seniority intact. This would effectively prevent

the roads from making any compromise, if the report proves true.

The shopmen still believe that they can win the strike in spite of the fact that there has been thus far no vital delay in transportation. The action of the Interstate Commerce Commission in re-establishing priority ruling on essential commodities has gone a long way toward saving the situation.

At the present time the strike is confined to a relatively small fraction of the total railroad employees. It can hardly succeed without the support of the rest of the employees and of the general public. Public support, the strike is hardly likely to get, since practically everyone outside of the unions has suffered more from the business readjustments of the last year than those inside.

The brotherhoods of the engineers, firemen, conductors and trainmen are none too anxious to fight the shopmen's battle for them. The brotherhoods did not benefit as much from the dictatorship of labor during the post-war boom as did the other unions. Since they did not receive unusually high advances they are not so likely to be forced to accept a wage cut under present conditions, and thus there is no great incentive for them to back up the strikers. A consensus of opinion seems to be that the strike leaders have recognized that a mistake was made in calling the strike and that they are willing to accept the offer of arbitration proposed by President Harding if it will give them a chance to save their faces.

If the railroad executives can secure a return of the men at an early date on the basis of the wage scale announced by the Labor Board it is probable that they will effect some sort of a compromise on the seniority ruling, since this is by no means the important point at issue.

With both sides fundamentally ready to end the struggle it would seem to be merely a matter of days before the men are back at work.

Coal Reserves Steadily Dwindling

THE coal strike shows few signs of coming to an end. The fundamental differences between the miners and operators indicate that there is still a long fight ahead. There is already a very serious shortage of fuel west of the Mississippi, especially in the Northwest. Reserves in New England are steadily dwindling and the seriousness of the situation can hardly be exaggerated. A curtailment of rail and industrial operations from lack of coal is imminent.

It is hardly possible to get enough fuel into the Northwest by water to take care of the requirements through winter and consequently traffic on the roads running West from the coal mining regions will be overloaded this fall and winter. On July 25, the Interstate Commerce Commission issued priority orders similar to those in effect during the war. Railroads and steamship lines are entitled to first supplies and public utilities come second on the list. The priority arrangement is necessary to make fuel distribution as effective as possible during the slowing up of transportation due to the shopmen's strike but it will doubtless be continued even if the rail strike is settled until conditions resume at least a semblance of normal.

The Administration apparently planned to let the strike go as far as possible before interfering in the hope that the operators could produce enough coal to carry the country through the fall and winter. Even with the elaborate program for the importation of foreign coal this seems impossible and the situation therefore resolves itself into one of devising some means of getting the miners back to work. The President's invitation to the operators to open their mines has had practically no effect on the anthracite production and little on the bituminous situation. The production of bituminous is still under 4,000,000 tons a week. According to the geological survey our consumption is approximately 8,000,000 tons a week. Importation is on a very small scale and could not possibly hope to make up the balance.

Some of the miners originally felt that inasmuch as they were forced to remain idle a certain portion of the year in any event, they might take that term of idleness during a strike as well as at any other time. But they have begun to feel the financial effects of a long period of enforced idleness. It is reported that suffering in the Pennsylvania, West Virginia, and Illinois fields has been becoming more acute each day.

Since indications point to an early settlement of the rail strike Administration efforts are now being focused in this direction. It is anticipated that within the next week or 10 days, the rail strike will be settled and attention will be directed entirely to the coal situation. The present plan seems to be the appointment of a coal commission with powers equal to the Interstate Commerce Commission in the fuel field or the giving of plenary powers to the latter commission to deal with coal in accordance with the emergency. Unless something unexpected turns up, there does not seem to be much hope for a settlement of the coal strike before the first of September. By that time we will be facing a severe famine and unless the strike is settled shortly after that date we will probably be faced with the necessity of shutting down some of our industrial plants.

The priority orders have made it difficult for manufacturers in those industries not favored by the ruling, to estimate their production in advance. If coal rationing is to be continued for any length of time, it is certain to result in the cancellation of many orders of goods for future delivery. Particularly is this true in case of those factories now at work on orders for Christmas and holiday articles.

Another month will see these industries represented at Washington by manufacturers insisting on a modification of the priority orders under the plea that they must have coal, and in reasonable quantities, if they are to remain in business.

Intervention Never Seems the Same to Both Sides

A protected industry.

What Makes the Wheels Go 'Round? The Power Problem Analyzed

WHAT will happen if the coal strike continues? How long is it likely to last? What are our fuel resources? How soon will they be exhausted? Is the trend of power generation toward hydro-electric plants or is steam being used more than ever? How large a part does fuel oil play in our industrial life? What is the most efficient method of producing power from coal?

These are some of the questions which are answered in this issue, in a searching analysis of our coal, oil, gas and water power resources.

Knowledge of fundamental factors in our power problem is more important today than ever before.

THE INDUSTRIAL DIGEST presents this analysis in the hope that it may serve to clarify some of the elements which are under constant discussion in these days.—*The Editor.*

POWER is the lifeblood of industry. Without power our factories could not run, our workers could not draw pay envelopes and consumers could not purchase manufactured goods. So it is that a crisis in power affects everyone intimately.

The country is facing a power crisis at present. During the last four months, most of the nation's coal mines have been idle—and coal, practically speaking, is power. Even should the coal strike stop today, which does not seem likely at this writing, it is certain that there will be a fuel famine in the fall.

Some coal is being mined, and of course we are not threatened with the loss of our entire power supply, yet the imminent exhausting of our coal reserves means that when manufacturers wish to start ahead full speed in the fall, they are likely to be held up. Coal will probably cost more than if there had been no strike, and consequently goods will cost more. Business will not be so good as it would otherwise have been. People will have less to eat, to wear, to spend. . . . All because of the partial failure of the power supply upon

which the structure of our entire modern civilization is built.

It is important, therefore, to examine carefully into our power resources; the means by which they are developed, and the probable effect of their future development upon industry as a whole and individual plants in particular. Such an analysis cannot but be helpful in presenting a clearer picture of the situation, and consequently a better understanding of the probable developments from the standpoint of the manufacturer.

The chief source of the energy upon which industry depends is, of course, coal. Second in importance is waterpower, and in addition we have petroleum and natural gas. From one point of view petroleum might be considered more important than waterpower, for at present it is more widely used; but it is chiefly used for power in the form of gasoline for non-industrial or semi-industrial purposes. From the viewpoint of our future development, moreover, waterpower is of tremendous importance and is receiving a measure of the attention to which it is entitled.

The energy resources per capita possessed by the people

of the United States, according to C. G. Gilbert and J. E. Pogue in *America's Power Resources*, are as follows:

	Produced Annually	Used to Date	Unused
Coal	6.5 tons	141 tons	35,000 tons
Petroleum	4.4 barrels	54 barrels	59 barrels
Natural Gas.....	Equivalent of 0.3 ton coal	Impossible to estimate	Impossible to esti- mate
Waterpower	Equivalent of 0.4 ton coal	Impossible to estimate	Equivalent of 3.6 to 12 tons coal per year

Dr. George Otis Smith, director of the U. S. Geological Survey, expresses as follows the amount of power used by American industry:

"For contrast with the present era of machine-aided civilization we naturally turn to the days of ancient Rome or Greece or Egypt, when hordes of slaves toiled both in the erection of those great monuments that have been called the 'wonders of the world' and the performance of the daily tasks of providing the necessities and luxuries of that age. Man power then made use of only the simplest laws of mechanics.

"I find that several writers on the subject of power have estimated the number of energy servants in our employ, and these estimates are based upon the installed capacity of our prime movers, which is approximately 100 million horsepower, or nearly one horsepower to each man, woman, and child, in the United States. Using the equivalent of ten man-power hours to the horsepower-hour we find in this the suggestion that we each have the equivalent of ten servants to do our bidding. But even mechanical power has some of the frailties of human power: capacity and performance are rarely equal. So, if we take the statistics of the energy output that we really utilize we discover that these energy servants work very short days, for, with the exception of the electric utilities, our prime movers do not give us anything like the equivalent of an 8-hour day in terms of their rated capacity. The steam locomotives, which represent perhaps 60% of the total installed capacity, average only about a 7% use factor, which brings down the average load factor to not much over 14%.

"These workers, represented by the water turbine and the steam engine, are tireless, it is true, and they are able to render continuous service as man power cannot, yet the fact is that we do not so use them. We may figure that we each have ten energy servants to help us in the world's work, but as they average only about 23½ hours a week a better statement would be that we each of us have the equivalent of five slaves working for us day by day. You will note that this estimate is arrived at by figuring that with a 14% load factor it takes nearly two installed horsepower to equal one continuous horsepower for the human week of 44 hours. This quota of five energy servants for each of us is far in excess of what the Greeks possessed in the form of human slaves, five helots being, I understand, the power equipment of the average Greek freedman's family, or nearer one apiece, when Greek culture rested on a substratum of slave labor."

Comparing the extent of our resources in coal, waterpower and oil, the three chief sources of power, Dr. Smith says:

"If we take 50,000,000 horsepower as an average figure for the potential waterpower of the United States, without storage, we find that if fully de-

veloped and if used at the average load factor of today our rivers and streams would just about meet the country's present needs and would supply that amount of power for all time; moreover, with storage and an improved load factor they could provide a considerably increased output of energy to meet the growing demand.

"Now if, leaving our waterpower resources to one side, we try putting the whole power burden on our coal mines we are able to make a direct comparison between our coal resources and our potential waterpowers. There is in the United States accessible and available for future use an aggregate of about 2500 billion tons of coal, not including lignite. Only about one-fifth of this is in the Eastern States, another fifth is in the coal fields of the Central States, and nearly three-fifths is in the coal fields of the Central States, and nearly three-fifths is in the Rocky Mountain and Western States. In converting these great reserves of coal into power I found myself using a new unit, the horsepower-century, for which the equivalent in Eastern coal is 250 tons, in interior coal 300 tons, and in Western coal 350 tons. By applying these factors to our estimates of reserves we get 2240 million horsepower-centuries, 1750 million horsepower-centuries, and 4171 million horsepower-centuries, respectively, or a total of 8161 million horsepower-centuries. I should add that a million horsepower-centuries is seven times the present power output of the United States. So you will see that by adopting the best steam practice of today the present power requirements of this country could be met with coal for 57,000 years, although we know that long before the end of that period the greater depth of the coal mines and their increased distance from market would alone create power demands for mining and transportation that would considerably cut down the amount of power available for other uses.

"We measure the petroleum wealth of the United States by billions of barrels—about 5 billion already produced in the last 60 years, and about 7 billion left for the future. Again adopting the best steam practice of today in public-utility stations of Texas and California—a little less than 32 barrels to the horsepower-year—and trying to carry the whole power load of the country with oil alone, we find that the oil reserves of the United States, although measured by billions of barrels, would last only 9 years and 3 months. Without allowing for the fact that steam raising for power is only one of the many uses of coal, these two figures, 57,000 and 9¼ years, are sufficiently impressive to make us fairly receptive to the general truth of the statement: We have just as much real chance of replacing coal by oil as we have of finding enough gold to use it in place of steel."

Coal, then, is the primary source of our industrial power. It will probably remain in this position for many years. The increased use of oil as fuel and the development of waterpower will supplement coal, but can hardly replace it.

The United States consumes something like two-thirds of a billion tons of coal a year. Charles P. Steinmetz made possible the comprehension of this enormous figure by making this comparison:

"One of the great wonders of the world is the Chinese Wall, running across the country for hundreds of miles, by means of which China unsuccessfully tried to protect its northern frontier against invasion. Using the coal produced in one year as building material, we could with

The engine-room of a modern, steam-driven factory

Typical transportation demand of the soft coal industry. When business is fairly active, our annual requirements for home consumption and export are about 528,000,000 tons per year. The diagram shows the monthly quotas in which this total is likely to be called for by the consumer, as indicated by the experience of the past eight years.—(Survey Graphic.)

it build a wall like the Chinese Wall, all around the United States, following the Canadian and Mexican frontiers, the Atlantic, Gulf and Pacific Coast; and with the chemical energy contained in the next year's coal production we could lift this entire wall into space, 200 miles high. Or, with the coal produced in one year used as building material, we could build 400 pyramids, larger than the largest pyramid of Egypt."

There is coal in the ground under nearly 500,000 square miles of the United States. Most of that which is mined, however, comes from a few regions where the deposits are high grade and which are situated in economically strategic positions. Nearly all the anthracite mined comes from an area about 500 miles square in northeastern Pennsylvania. The important bituminous areas are the Appalachian field, which runs from Pennsylvania to Alabama and supplies the iron and steel industries and the great manufacturing centers of the East; a field in the interior extending from Michigan to Texas, whose coal, for the most part, is not nearly as high grade as that of the Appalachian field and which has been worked chiefly in Illinois; and the fields of the great plains and the Rocky Mountains, whose coal is almost all low grade,

with a few deposits of high grade that are now being worked. About a quarter of the coal mined so far has come from the Appalachian field, a fifth from the Michigan-Texas region, and not quite one-tenth from the field further west.

The Trouble with Coal Mining

IF coal of all grades is considered, the supply underground is almost unlimited. Less than one-half of one per cent. of our total reserves have been touched. But in view of our present industrial practice the important question is not: "How long will our total coal reserves last?" but "How long can we continue to dig the kind of coal we're getting now and burn it in the way we are now using it?" The answer to the latter question has been given by M. R. Campbell, of the United States Geological Survey, who says: "Before long, perhaps within 50 years, much of the high-rank coal in the United States will be exhausted."

We are now being shown, to our pain, that there are many things the matter with the methods we use in mining this coal of ours. The periodic disorders which frighten the country, and often, as in the present case, really menace chances of prosperity, are evidence that the industry is not organized as it should be. Gilbert and Pogue sum up the difficulties with the coal industry as follows:

"Bituminous coal mining as an industry is beset by conditions which are the occasion of present wastefulness and the justification of apprehension for the future. Scattered and unorganized, most of the individual companies are small and financially weak; inadequate cooperation in engineering practice exists; new technical developments are slow of growth; coal is mined for the most part by obsolescent, long-established methods. With no means of storage developed, the average mine can produce coal only when railway cars stand ready to receive it; a fluctuating demand, accentuated by seasonal variations, leads to instability of operations; many mines must close down in slack months, with destructive effect on the conditions and supply of labor. The supply of labor also is not equal to the capacity of the developed mines; hence a labor shortage always develops in periods of prosperity, when the demand for coal suddenly increases.

"For years, until recently, the price of coal at the mine ranged from \$1 to \$1.15 a ton, a figure so low that only the best and most easily obtainable coal could be extracted by the cheapest method of mining, irrespective of the waste involved. The tonnage of thin-seam and high-cost areas sacrificed in the process amounts to more than half the total coal produced to

General view of the Chicago By-product Coke Co. plant, designed

date. Many districts have been burdened with a leasing system that obligated the company to remove a given tonnage each year, irrespective of market demand or price, with the result that the richest portions were drawn from seam after seam with irretrievable loss to present needs. The fixing of wages on the basis of thick and easily worked seams has imposed severe penalties upon inferior conditions, precluding the introduction of new and improved methods. Added to this, the policy of the Government, as exemplified in its anti-trust laws, has forbidden combinations and restrained co-operation, with the result that large-scale, standardized operations, a paramount and distinctive American achievement, are virtually lacking in the mining of coal.

"The trouble with coal-mining is too much competition, resulting in a lack of balance between production, transportation, and distribution. Coal-bearing land is so abundant in the United States that an excessive number of mines have been developed. The productive capacity of the coal industry, in consequence, is far in excess of the requirements of the country. In addition, the demand for coal varies so from summer to winter that for the past 30 years the average working year has been only 215 days in length, leaving 93 possible working days when the mines were idle. Fluctuating operations have also created problems in the allocation of coal-cars, with enforced idleness in summer and congestion in winter. In times of slack demand, labor and equipment in large volume are forced out of employment. Depressed periods, in turn, are invariably followed by a hysterical demand and frenzied competition on the part of consumers, who are apt to place orders far in excess of their requirements. The coal industry is unstable, speculative, and unreliable alike to producer and consumer. The crying need is for stabilization. With proper operation, an excess mine capacity of some 150,000,000 to 200,000,000 tons and an excess labor force of some 150,000 men could be eliminated."

The problem of the transportation of coal is the most difficult which arises in connection with the fuel supply. Power at the mine is of no use to anyone; it must be carried to the factory where it is to be used. At present this job is done by

(Gas Age-Record)

A typical gas tank with 2,000,000 cu. ft. capacity.

the railroads, one-third of whose freight is coal. This is a tremendous burden for our badly strained railroad system, which at best is inflexible and troublesome. This situation is complicated by the facts that the railroads themselves use a large proportion of the coal they carry, and the capital which controls the roads often overlaps with that which controls the coal mines. This will make more difficult a scientific revision of our method of supplying coal-derived power to industry.

But as the power situation grows worse, as it will if it follows its present trend, something will have to be done.

The Remedy

THE most obvious remedy is the reorganization of the coal mining industry from a business point of view, in such a way that the unevenness of production and the labor troubles will be ironed out. It is quite conceivable that the present crises will force an attempt to find a solution along these lines.

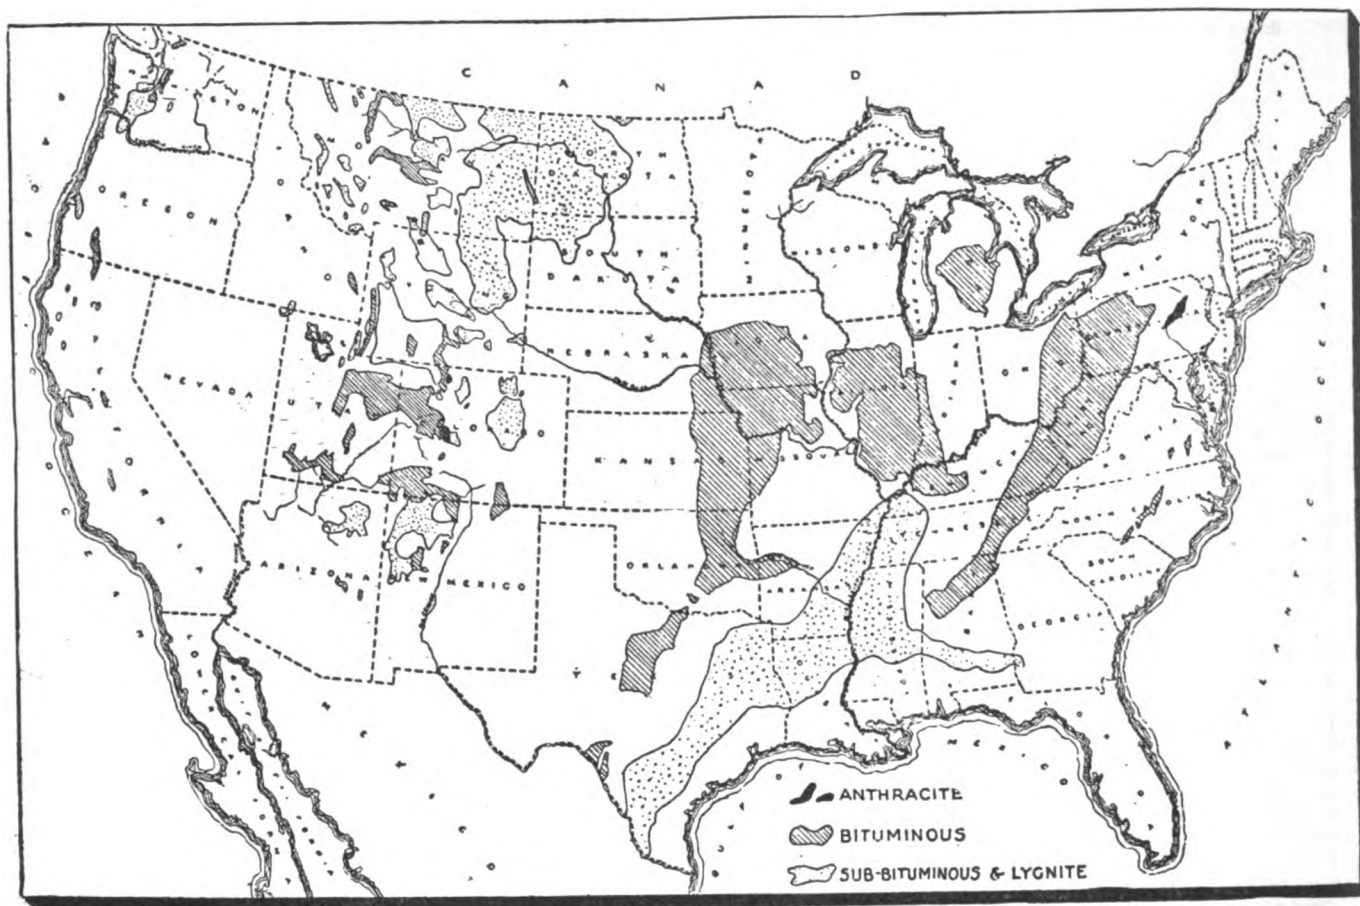

In the long run, however, the problem will have to be approached from a far more profound point of view. If our supply of high-grade coal is sufficient to last us for only 50 years, something will have to be done during the life of the present generation to relieve the strain on this source of power. Our methods of using coal will have to be made more efficient, and the other sources of energy, oil and water-power, will have to be developed. Engineers are now tremendously interested in these problems, and when industry is ready to cope with them, the technical solutions will undoubtedly be waiting.

Engineers point out, in the first place, that we are wasting our coal by not removing from it all the valuable by-products which go up in smoke when coal is burned under boilers. These by-products, which can be manufactured into a great variety of commodities ranging from medicines to explosives,

(Gas Age-Record)

to have a daily capacity of 100,000,000 cu. ft. of gas.

(Century Co.)

This map shows the geographical location of our principal coal resources.

can be reclaimed when coal is "coked" in the process of manufacturing coke or gas.

It is ridiculous, engineers say, to burn raw coal for fuel. Take the by-products out and then burn the coke, they suggest. If we give up the idea that we must burn raw coal we shall be able to use the lower grades of the fuel, in the form of briquets or gas. This is now practiced in Europe.

How to Use Coal Efficiently

BEHIND most schemes for improving our methods of using coal is this central idea: the coal should no longer be carried whole to the point where the power is to be consumed. It should be converted into some less solid form of energy at a central station, either at the mine mouth or at some strategic point for the supplying of power to a large district.

Floyd W. Parsons, writer on industrial subjects and editorial director of the *Gas Age-Record*, believes that the problem can be solved by converting the coal into both gas and electricity at the mine mouth. The gas, he says, should be carried in welded pipes from the mines to the factories, just as petroleum is now piped over great distances. It should be used for industrial processes requiring great heat, for which power in the form of electricity is uneconomical. The coke which will remain after the gas and other by-products have been extracted should be placed, while still white hot, under boilers which will supply the steam for the generation of electricity. This can be carried over electrical conduits to factories which need it for motive power. This ideal scheme will eliminate the railways entirely from the transportation of power.

Even if our coal resources could be used with maximum efficiency, according to some such scheme as that suggested by Mr. Parsons, it would still be necessary to supplement this fuel by using to the fullest possible extent our other power resources—oil, waterpower, and to a more limited degree, natural gas.

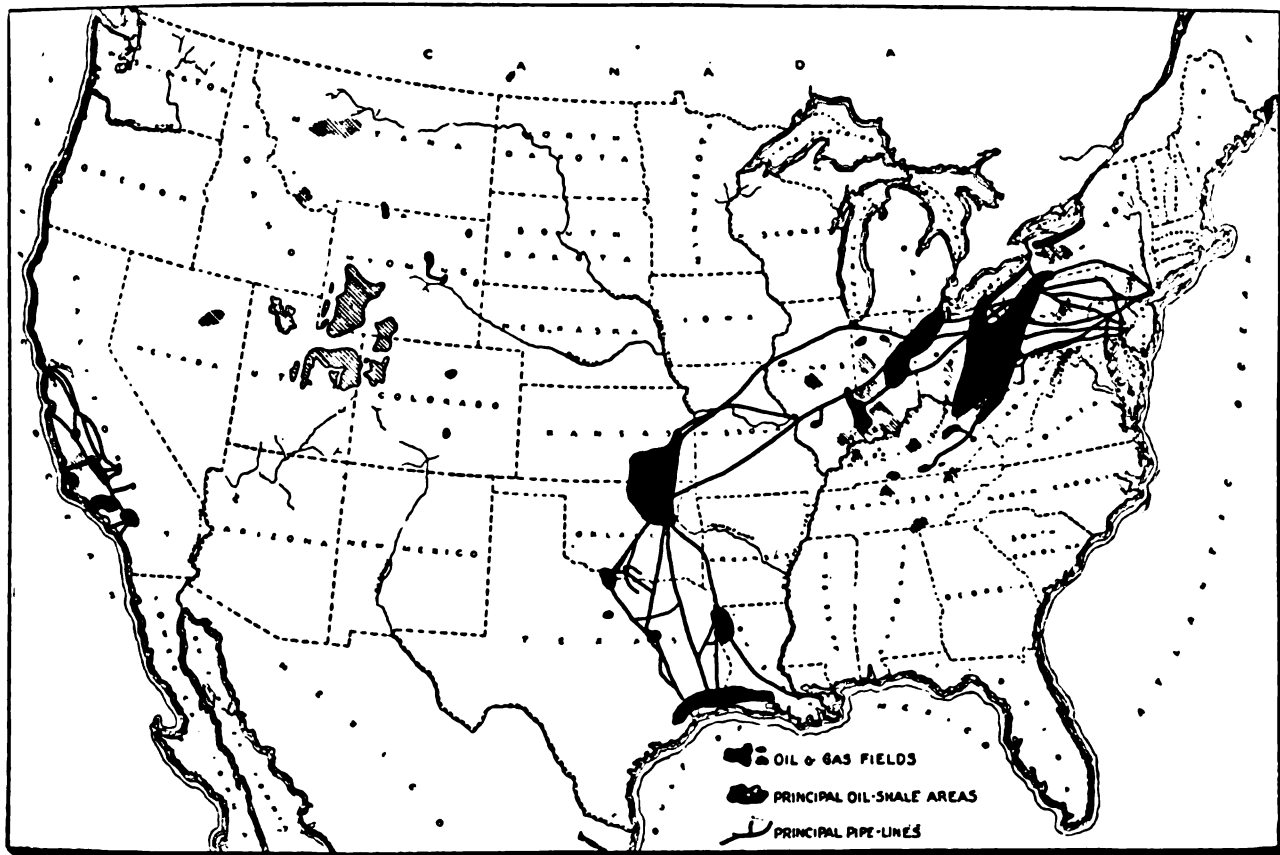

The U. S. Geological Survey recently estimated that the total

oil reserves of the country amount to 9,150,000,000 barrels of 42 gallons each. These reserves are distributed among the States as follows:

	Millions of barrels
New York	100
Pennsylvania	260
West Virginia	200
Ohio	190
Indiana and Michigan	70
Illinois	440
Kentucky, Tennessee, northern Alabama, and northeastern Mississippi	175
Missouri, Iowa, North Dakota, Wisconsin and Minnesota	40
Kansas	425
Oklahoma	1,340
Northern Louisiana and Arkansas	525
Texas, except Gulf coast	2,100
Colorado, New Mexico, and Arizona	50
Wyoming	525
Montana, Nebraska, and South Dakota	100
Utah, Nevada, Oregon, Washington, and Idaho	80
California	1,850
Eastern Gulf coastal plain and Atlantic Coast States	10
	<hr/> 9,150

"Of these 9,150,000,000 bbl. of oil over 4,000,000,000 bbl. are in the heavy-oil group, including fuel oils, and 5,000,000,000 bbl. in the light-oil classes," says David White, chief geologist of the U. S. Geological Survey. "The Lima-Indiana field is credited with 40,000,000 bbl., and approximately 725,000,000 bbl. are believed to remain in the Appalachian States. These estimates relate to oil in the ground recoverable by present methods. It was the unanimous conclusion of the committee that except for small areas in western New York and northern Pennsylvania where 'water drive' has long been in operation, any attempt to forecast quantitatively the increased recovery, perhaps 40-80% to be won in the different regions, fields, and pools by improved methods of recovery would introduce an element of uncertainty far greater than that entering into the present estimates.

"The total exceeds the estimate last published by the writer by 2,000,000,000 bbl. The anomaly of growing estimates simultaneous with exhausting resources is explained by the widespread wildcatting during and since the war; by the vastly greater volume of information touching all areas available for use by a larger and more diverse body of oil geologists in the

This map shows geographical location of the principal gas and oil fields of the U. S.

(Century Co.)

committee; by the more thorough methods of calculating oil reserves and the experience developed in their use; and by the fact that the earlier estimates were far more conservative.

"It is more than probable that, in most instances, the actual yields of the producing States will exceed the estimates, but it is equally probable that for the older producing States the excess will not be large compared to the whole amount. Greater uncertainty attends, of course, the States of present small production and less complete exploration and development.

"It may be noted that the oil reserves of the United States, as estimated by the committee, comprise one-seventh of the oil reserves of the world, as estimated by Stebinger and White. From these figures, it would appear that this country, with an original content of about 14,000,000,000 bbl., was much fuller of oil than other parts of the earth or, which is more probable, the estimates for some of the other countries are too low.

"Contrary to the statement that the oil reserves of the United States will be exhausted in 20 years, a long time will be required for the exhaustion of our oil fields. Though the estimated reserves would not survive 20 years if they could be made available so quickly as to meet the demands, even at the present rate of consumption, some of the oil pools are not likely to be discovered within a generation and some will be producing 75 years from now. Therefore, if the oil cannot be so rapidly found and extracted from the ground, we must the sooner pass a point beyond which will follow a long, though naturally variable, decline."

"As our domestic production has been increasing annually a little more than 6%, during normal years, with occasional special jumps, a much larger increase in the amount of imported oil has been necessary to fill the gap between domestic production and domestic requirements. While the output of the fields in the United States in 1913 was 248,000,000 bbl., an 11% increase over that of the preceding year; in 1918, 356,000,000 bbl., 6% increase; 1919, 378,000,000 bbl., 6% increase; 1920, 443,000,000 bbl., 17% increase; and 1921, 470,000,000 bbl., 6.1% increase; our importations of petroleum, mainly from Mexico, for the same years were, respectively, 18,000,000 bbl., 141% increase; 38,000,000 bbl., 25% increase; 53,000,000 bbl., 40% increase; 106,000,000 bbl., 101% increase; and 125,000,000 bbl., 18.2% increase. The situation is as alarming as it is striking."

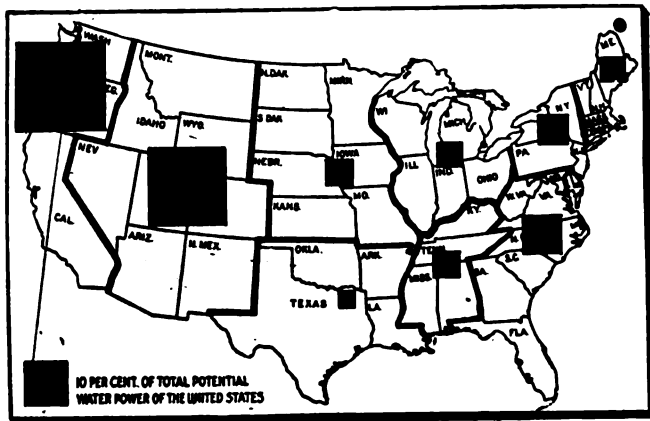

The use of oil as an industrial fuel was stimulated during the war, when the need to use all available power resources was brought forcefully before the country. The coal famine of 1917-18 so accentuated the demand for fuel oil that the character of the oil-refining industry was changed, and fuel oil replaced gasoline as the leading petroleum product. This situation did not survive the war, and the demand for fuel oil soon dropped. Experts now predict that the petroleum industry will have difficulty in keeping up with the call for gasoline, and that eventually all the petroleum used as fuel will be burned in internal combustion engines, which are not of prime importance from the industrial viewpoint.

Fuel oil today is used chiefly in the Southwest and on the Pacific Coast, where coal is scarce. It is used extensively on railway locomotives and in electrical central stations, and, to a lesser degree, in individual industrial plants. Its use, industrially, undoubtedly will grow, although it cannot be compared in importance as a power source with coal and waterpower.

The Outlook for Natural Gas

THE same is true of natural gas. Two-thirds of the nation's total annual output of natural gas—about 600,000,000,000 cubic feet—is burned in manufacturing plants under steam boilers, or used by manufacturers of glass, cement, pottery and other products that require intense heat. The production of gas, however, is declining, and its use, while important, is confined to parts of the country where it occurs in abundance.

Coal's true auxiliary as the chief source of our future supply of energy is waterpower. The total potential waterpower of the country is estimated at anywhere from 100,000,000 to 200,000,000 h.p., of which about 50,000,000 can be used without special provision for storage. This is spread over almost the entire country. Sections without coal resources, such as New England, the South Atlantic States and the Pacific slope, have the greatest abundance of waterpower,

The distribution of waterpower resources in the U. S.

so that the development of this resource would mean the more equitable distribution of power, and therefore of industrial opportunity, among the potential manufacturing States of the Union.

The development of this waterpower has been slow. The total amount of energy consumed in the United States has increased greatly in recent years, but only about 10% of the increased demand has been met by the development of waterpower. Today the hydroelectricity produced is the equivalent of about 55,000,000 tons of coal annually, whereas nearly 400,000,000 tons are used to produce steam power directly applied or used for the generation of electricity.

The slowness of this development is due to a number of unavoidable difficulties. Federal restrictions, which make necessary the issuance of Government permits before some 75% or 80% of the potential waterpower can be developed, have increased the sluggishness of growth. But more important is the fact that the cream of our coal and oil supplies can be tapped more easily than our waterpower reserves. The use of fuel, moreover, is sanctioned by habit and historical development. A waterpower development involves a heavy initial expenditure, whereas the first cost of a steam plant is comparatively low, and the greater expenses of fuel can be carried along from year to year. Great waterpower projects are likely to meet with public objection if there is any reason to suspect that they will endanger the scenic beauty of a river or a waterfall. For all these reasons the development of waterpower is slow.

The Power Engineer's Ideal

MOST engineers believe that the central station transmitting electrical power is the device which will make possible the fullest and most economical use of our resources. The waterpower of the nation can be used extensively only if central stations are employed; and engineers believe that coal can be burned more economically in generating plants supplying relatively large areas than in individual factories. The combination of water-driven central stations with coal-driven central stations, in a system blanketing the United States, is the engineer's dream of efficient power production for the nation.

Forward-looking engineers in the industrial power field are now getting their technical equipment ready for the installation of such a system.

"In a large industrial district with which the writer is familiar there is a large load ready and waiting to be connected with the central-station systems, and were there a wholly adequate and reliable supply of power at the disposal of the power companies in this territory, their present large aggregate load would be greatly increased," said Col. John Price Jackson, in a paper read before the American Society of Mechanical Engineers.

"Expressed opinions of industrial and central-station men, as well as various statistics, justify the conclusion that an equally pressing situation exists in most or all of our important industrial centers.

"The shortage of central power is serious by reason of the fact that it interferes materially with the natural productive growth of our country and with the prosperity of its several communities. Another even more serious element relating to such power shortage is the fact that it continues the use of a large number of isolated steam and electrical plants, most of which are consuming from two to four times the amount of fuel which would be required were the power supplied from efficient central stations. Moreover, the lack of sufficiently adequate central power systems makes impossible the economic utilization of many water powers which would become available if they could pump their power in the form of electrical energy into great electrical distribution systems having heavy demands.

"To so develop the central power systems within a reasonably short time that they will meet the present deficiency, absorb the great amount of unconnected or isolated loads, care for the natural growth of demand, and utilize our fuels and water powers most advantageously, represents, in this country, a problem of gigantic dimensions which will require much wisdom to solve."

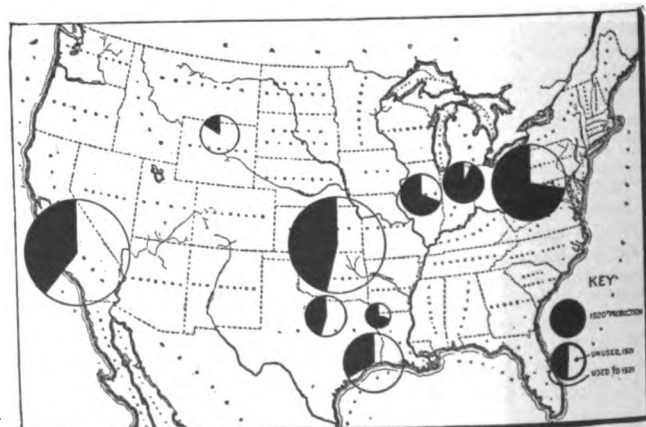

In Col. Jackson's opinion, the following factors toward the development of a central station system should be thoroughly considered by competent power men:

"1. To so arrange by interconnection of transmission systems and otherwise that the maximum amount of waterpower may be developed. The amount of waterpower utilized can and will greatly increase with the rapidly growing power demands, but in many important industrial sections of the country, where waterpower is scarce, it will require much wisdom to cause the increase to become a greater percentage of the total power than now exists. Many watersheds having reasonably constant flow, however, but not accessible for con-

The eclipse of petroleum. Map shows the relative degree of exhaustion of the principal oil-fields of the U. S.

nection normally with central power systems, can possibly become of early value for developing the electrochemical processes of the country, and incidentally in reducing the consumption of fuel.

"2. To place steam plants, as far as possible, close to coal mines or on waterways in order that energy may be transmitted as much as possible in the form of electric power rather than in the form of coal, with resultant reductions of freight charges and relief to railroad traffic.

"3. To supply practically all industries with power from central power systems, which would result not only in an enormous coal saving, but also in a large saving in man power, maintenance supplies, and in transportation.

"4. To largely electrify the railways. This would make possible a great reduction in the fuel used for transportation purposes and relieve the railroads from carrying a large dead weight of coal freight for their own purposes, and also would make available the materially increased duty of railroad trackage and equipment which is possible by electrification.

"5. To not only make the central stations adequate for all of the above purposes and the expected future growth, but fully reliable.

"6. To conserve a larger proportion of the valuable chemical constituents in the coal; such products are now recovered from only a small percentage of the total coal mined. Closely related with this problem is the conservation of our oil and natural-gas supplies. A discussion of these problems is not directly within the sphere of this paper, but it is believed that the suggestions for power development contained herein are along lines to coördinate with their solution.

"7. To work out programs which will enable the financing of our power systems to be handled with facility. By the census there were three billion dollars invested in 1917 in the central-station industry, not including electric railways. About double that is needed now or as soon as the equipment can be produced, say, in 1922 or soon thereafter, and at least four times the 1917 capital will be required well before 1930 if reasonable progress is made."

The super-power plan, developed by the U. S. Geological Survey, contemplates the installation of such a system in the industrial States of the northeast Atlantic Seaboard, W. S.

(Galloway)

Some of the largest turbo-generators in the world handling peak loads at Spokane, Wash.

Murray, a New York consulting electrical engineer, summarizes as follows the effect of the super-power plan:

"It provides a means," he says, "by which, conservatively speaking, one ton of coal will do the work of two, and the railroads within the zone, and those carrying coal into the zone will be relieved of transporting one-half the amount of coal required for power and lighting purposes. In short, the value of machine capacity from a utilization standpoint will be increased three to fourfold, and coal resources for the purposes named conserved twofold.

"This means that a present plant capacity of 17,000,000 h. p. can be replaced by one of not greater than 5,500,000 h. p., and that not less than 30,000,000 tons of coal per annum can be saved, which at \$5 a ton will represent \$150,000,000 a year.

"Besides the above savings, two great departments of economy will be created; one applying both to the railroads and the industries, in the reduced cost of maintenance of machinery, and the other applying

to the railroads alone, in the reduction of train miles, by virtue of this plan permitting consolidation of trains with resultant savings in train miles. It is estimated that these latter economies will effect a saving of another \$150,000,000 annually, thus making a total saving of \$300,000,000."

A Storehouse of Electric Energy

THIS is to be accomplished through the operation of a main 250,000 volt line connecting Washington or Baltimore with Boston via Wilmington, Philadelphia, Newark, New York, New Haven and Providence. The line is to be fed by three groups of large power stations, situated from 150 to 250 miles from the main transmission line. The first of these groups is to be built in the bituminous coal fields, at some location near a supply of water for condensation. The second will be in the Pennsylvania anthracite fields, and the third will be on the St. Lawrence River. The main line will be tapped by all the large industrial centers as well as by practically all the railroads along its route.

"The three generating groups would supply the
